A clinical evaluation of trichomoniasis in San Jose, Costa Rica using the InPouch TV test

K A Borchardt, V Hernandez, S Miller, K Loaiciga, L Cruz, S Naranjo, N Maida

Abstract

Objective—to determine the prevalence of trichomoniasis in San Jose, Costa Rica, comparing two methods, the InPouch™ TV test and the saline wet mount.

Methods—One hundred symptomatic and asymptomatic female patients at two hospitals and at a sexually transmitted disease (STD) clinic were evaluated. Vaginal discharge was the most prevalent genitourinary abnormality among symptomatic patients. The patients were between 18 and 70 years old. Fifty-seven were from the STD clinic, 43 from the two hospitals. A saline wet mount and a culture were taken from each patient. The culture employed a new procedure for diagnosis of trichomonads, the InPouch™ TV test (BioMed Diagnostics, San Jose, CA).

Results—Thirteen of the 100 patients were culture positive, two of whom were wet mount positive. No wet mount positives were culture negative. Eleven of the positive tests were from the STD clinic and two were from the hospitals.

Conclusions—The results of this initial epidemiologic study indicate a prevalence of 19% for trichomoniasis in the STD clinic population and 4.6% in the hospitals group. *Trichomonas vaginalis* was not diagnosed by laboratory methods prior to this study. The InPouch™ TV test has a selective fungicidal and bactericidal, enriched proteose-peptone medium which provides a sensitivity of 4 organisms per ml and a 1 year shelf life at room temperature. This in vitro culture test demonstrated unique capabilities as a transport and culture medium. Its procedure offers simplicity in application and an excellent visualisation of trichomonads.

Introduction

The flagellated protozoan, *Trichomonas vaginalis*, is the aetiological agent in one of the most frequently occurring sexually transmitted diseases (STDs). Annually an estimated 180 million cases occur worldwide.¹ Although trichomoniasis in women may be symptomatic and produce vulvar itching, a purulent discharge, and red punctate areas on the vaginal and cervical mucosa, clinical findings indicate that as many as 50% of patients are asymptomatic.² Most infected male patients remain asymptomatic.³

In both Central and South America, epidemiological data are not available as to the

prevalence of trichomoniasis or laboratory methods employed in diagnosis. Presently in Costa Rica, the Papanicolaou-stained gynaecological smear is used as an adjunct to clinical diagnosis.

This study is the first epidemiological investigation of trichomoniasis in San Jose, Costa Rica, evaluating both symptomatic and asymptomatic patients at three clinic sites. Patient specimens were examined by the saline wet mount and in vitro culture. The InPouch™ TV test for in vitro culturing of *T. vaginalis* was utilised. This method has previously demonstrated significant advantages over other culture procedures.⁴ This in vitro culture test has a selective fungicidal and bactericidal, enriched proteose-peptone medium which provides a sensitivity of 4 organisms per ml.⁴ The pouch test could not be compared with another in vitro test in this study because of laboratory constraints.

Materials and methods

The three clinic sites involved in this study were Hospital San Juan de Dios, Clinica Biblica, and Lucha Antivenerea de Costa Rica. One hundred symptomatic and asymptomatic patients were sampled for trichomoniasis. The patients' hospital number, age, and symptoms were recorded.

All wet mounts were performed by one of the authors (KAB) who is an experienced microscopist in protozoan infections. Sterile cotton-tipped swabs were used to obtain specimens from the posterior fornix of the vagina. Each swab was placed in a sterile glass tube containing 0.5 ml of sterile saline immediately after sampling. The specimen was eluted from the cotton swab by vigorously twirling the stem of the swab. The saline specimen was held at 27°C and evaluated within 60 minutes. A drop of the specimen was placed on a glass slide, cover slipped, and examined microscopically under low power ($\times 100$). Then the swab was placed in the saline mixture and used to

Table 2 Patients positive for *Trichomonas vaginalis*

Patient	Age (years)	Symptoms	Wet mount	Time culture positive
1	28	Asymptomatic	Positive	24 hours
2	32	Asymptomatic	Positive	24 hours
3	26	Vaginal discharge	Negative	24 hours
4	26	Vaginal discharge	Negative	24 hours
5	32	Vaginal discharge	Negative	24 hours
6	33	Asymptomatic	Negative	24 hours
7	33	Dyspareunia	Negative	24 hours
		Vaginal discharge		
		Itching		
8	55	Vaginal discharge	Negative	24 hours
9	47	Itching	Negative	48 hours
10	22	Vaginal discharge	Negative	5 days
		Yeast		
11	23	Vaginal discharge	Negative	5 days
12	45	Vaginal discharge	Negative	5 days
		Itching		
13	50	Unknown symptoms	Negative	5 days

Except for patient No 11 from Hospital San Juan de Dios and patient No 13 from Clinica Biblica, the others were from Lucha Antivenerea de Costa Rica.

inoculate the InPouch™ TV as previously described.⁴ Tests were incubated at 37°C, examined at 24 h and when negative at 48 h and 5 days.

Results

In this study, 100 symptomatic and asymptomatic female patients between the ages of 18 and 70 years were studied for trichomoniasis by saline wet mount and culture with the InPouch™ TV test. Table 1 presents the number of patients examined at each site and their clinical status. The majority of the patients, 57, were examined at the Lucha Antivenerea Costa Rica (the STD clinic). Twenty six patients were examined at the Hospital San Juan de Dios, and 17 at the Clinica Biblica. Four of the patients tested at Hospital San Juan de Dios and two at Clinica Biblica were diagnosed as positive for trichomoniasis by Papanicolaou smears. None of these six patients were positive either by saline wet mount or in vitro culture.

In Table 2, the patients positive for *T vaginalis* are listed as to their age, symptoms, which tests were positive, and the incubation period for a positive culture. Their ages ranged from 23 to 55 years, and three were asymptomatic. Two of the patients were both saline wet mount and culture positive. Eight of the cultures were positive within 24 h, 1 at 48 h, and 4 at 5 days.

Discussion

In evaluating a specimen for trichomonads by saline wet mount, the sensitivity of the test varies by the number of trichomonads present, the length of time the specimen has remained at room temperature, and the experience of the microscopist.⁵ The results of this study corroborate the importance of an in vitro culture for accurate diagnosis because only two of 13 patients were saline wet mount positive.

The InPouch™ TV test was used in this epidemiological evaluation in a tropical country because of the test's unique capabilities as a transport and culture medium, simplicity in application, and in excellent visualisation of trichomonads. Its sensitivity is 4 organisms for positive growth.⁴ Because of the antibacterial and antifungal agents in the medium, the test's specificity is significant even in patients with

polymicrobial infections.

The InPouch™ TV test can be used for rapid (18 h) diagnosis. A viewer is employed to immobilise the culture medium and allows the pouch to be evaluated within 2 minutes.⁴ The test is self-contained and requires nothing other than a microscope for viewing. Two other important advantages are that the medium has a 1 year shelf life at room temperature and the test can serve as a transport medium for several days while maintaining the viability of the trichomonads.

Six patients were diagnosed positive for trichomoniasis by cytological studies. None of these patients were either saline wet mount or culture positive. This confirms the findings of Thomason *et al*⁶ who reported that the Papanicolaou smear was the least specific and sensitive method of detecting *T vaginalis*. Negative saline wet mount tests for trichomonads in women demonstrate the lowest sensitivity and lowest positive predictive values and therefore may result in an incorrect diagnosis.⁵ Patients either in a low predictive setting or with negative wet mounts should have confirmation tests.⁵

Misdiagnosis of trichomoniasis is particularly important in patients who have had abdominal hysterectomies. Trichomoniasis vaginitis and bacterial vaginosis are risk factors for cuff cellulitis.⁷

An observation that positive trichomonad cultures were found in four patients who were 45, 47, 50, and 55 years of age indicates the possible prevalence of this infection in patients of that age. Two of these were diagnosed from out-patient clinics and the other were from the STD clinic. It could be important to quantitate their period of infection and potential nidus of infection. These represent unrecognised cases that could increase the incidence rate in the community.

The results of this study demonstrate that trichomoniasis presents a significant STD problem in Costa Rica in one group of patients examined at the STD clinic. The 19.2% of 57 patients who were positive represents an important reservoir of trichomoniasis in this population. It is important to emphasise that of the 100 patients tested in this study, the other 43 examined at the 2 hospitals were not all symptomatic for vaginal infections.
