Cefoperazone (Cefobid) for treating men with gonorrhoea caused by penicillinase producing Neisseria gonorrhoeae

JOONG HWAN KIM, YOUNG SUCK RO, AND YOUNG TAE KIM
From the Department of Dermatology, Hanyang University College of Medicine, Seoul, Korea

SUMMARY The recent emergence of spectinomycin resistant penicillinase producing Neisseria gonorrhoeae (PPNG) and the high prevalence of PPNG strains among the gonococcal isolates in Seoul represent a grave challenge to the programme for controlling sexually transmitted disease (STD).

Fifty men with uncomplicated gonococcal urethritis caused by PPNG strains were treated with a single intramuscular injection of 1 g cefoperazone. Forty two patients were followed up. All patients recovered including three who became reinfected and required further treatment. Two patients (4.8%) developed postgonococcal urethritis (PGU).

The MIC₉₀ of cefoperazone measured by an agar dilution susceptibility test was 0.12 mg/l.

Introduction

The ever decreasing sensitivity of Neisseria gonorrhoeae to various antibiotics has been noted throughout the world.¹ ² The high prevalence of penicillinase producing Neisseria gonorrhoeae (PPNG) strains among the isolates in Seoul has been a major problem. Spectinomycin has been recommended to treat uncomplicated gonococcal urethritis that has failed to respond to first line treatment and infections caused by PPNG strains. The recent appearance of spectinomycin resistant PPNG strains in Korea is a grave threat to the programme for controlling sexually transmitted diseases (STDs) and makes urgent an intensive search for an alternative treatment regimen.

Materials and methods

We studied men attending the STD clinic of Choong-Ku Health Center in Seoul during the four month period between March and July 1983 seeking treatment for urethral discharge. Only those patients with uncomplicated gonococcal urethritis were included in the study. A total of 699 patients attended the STD clinic during this period. Among 275 patients with gonorrhoea, 65 were found to have uncomplicated urethritis caused by PPNG strains. Of these, 50 were treated with cefoperazone 1 g intramuscularly and 42 patients were followed up. Their ages ranged between 19 and 49; the mean age was 25.5 and the median 25. Over 85% of the patients were under 30. Of the 42 men followed up, 22 (52.4%) had received previous treatment for their gonorrhoea, and 13 had been treated with penicillin shortly before treatment with cefoperazone.

TREATMENT

Each patient was given a single intramuscular injection of cefoperazone (Cefobid) 1 g, and was advised to refrain from sexual intercourse and to avoid taking other antibiotics and alcohol.

FOLLOW UP

Each patient was asked to attend the clinic for a test of cure three to five days after treatment with cefoperazone, when urethral smears were taken for Gram staining and microscopy and for culture. Patients who failed to attend were reminded by telephone. Defaulters who failed to attend after the initial treatment were excluded from the final assessment of the results.

FAILURE OF TREATMENT

Any patient showing intracellular Gram negative diplococci on Gram stained smear microscopy or a positive culture at the follow up visit without a history of further sexual contact, or both, was re-
Cefoperazone (Cefobid) to treat men with PPNG gonorrhoea

239

garded as a treatment failure. Any patient with a re-
currence who admitted having further sexual inter-
course since treatment was regarded as reinfected and
treated as a new case.

CRITERION OF CURE
At the follow up visit patients whose urethral smears
showed no Gram negative diplococci and gave
negative results on culture were considered to have
been cured.

POSTGONOCOCCAL URETHRITIS (PGU)
At the follow up visit a patient was considered to
have PGU if his urethral culture was negative and the
smear showed more than 20 leucocytes per high
power field or if there were more than 20 leucocytes
per high power field in the urinary sediment after
centrifuging at 600 × g for 15 minutes.10 11 14

DIAGNOSTIC TESTS
A urethral specimen was taken with a cotton tipped
wooden stick from each patient suspected of having
uncomplicated gonococcal infection, and was spread
over a slide for Gram staining. Another specimen
was inoculated on Thayer-Martin medium by Z
rolling, kept in a candle jar, and within two hours
cross streaked with a loop and incubated in a candle
jar at 35-36°C for 20-48 hours. A positive oxidase
reaction in colonies with typical morphology
composed of Gram negative diplococci was taken as
sufficient evidence of N gonorrhoeae. To detect
β-lactamase the chromogenic cephalosporin test was
used.8 10 12 14 15 The positive cultures were subcultured
on enriched chocolate agar, to which 2 mg/l sodium
penicillin G was added. The susceptibility of isolates
to cefoperazone, penicillin, tetracycline, and
spectinomycin was tested by the agar plate dilution
method.10 15 Serological tests for syphilis were per-
formed at the first visit.

SUSCEPTIBILITY TEST
Twofold concentrations of the antibiotics to be
tested were distributed into chocolate agar supple-
mented with Iso-vitalex. The test organisms were
suspended in Müller-Hinton broth. The suspension
turbidity was adjusted to correspond to 0-5
McFarland standard barium sulphate. The suspen-
sion was further diluted 100-fold, and each test
 suspension was inoculated on to the plates by a
replicator. The plates were incubated in a candle jar
at 35°C for 24 hours. The minimum inhibitory con-
centration (MIC) was the lowest concentration of
antibiotics that permitted the growth of no more
than one colony in each MIC determination. Strain
No K82-82 was used as the reference.

Results
All 42 patients were cured, including the three who
became reinfected. PGU was diagnosed in two
(4-8%). No side effects were reported. The
serological tests for syphilis gave negative results in
all cases at the first visit. The table shows the
susceptibilities of 40 isolates to various antibiotics.
The MICs of penicillin ranged from 4 mg/l to over 32
mg/l, with 26 (65%) of the 40 isolates having MICs
of >32 mg/l. The MICs of tetracycline were between
0.25 mg/l and 8 mg/l. The results showed that 80%
of strains were resistant to tetracycline. The MICs of
spectinomycin ranged from 4 mg/l to 16 mg/l. Cefoperazone MIC ranged between <0.015 mg/l to
>0.24 mg/l, with 34 (85%) of the 40 isolates having
MICs of up to 0.06 mg/l. The MIC90 of cefoperazone was 0.12 mg/l.

PPNG = penicillinase producing N gonorrhoeae.

Discussion
The appearance of PPNG strains in 197616 17
threatened the control of STD, which had already
been complicated by decreased susceptibility of N
gonorrhoeae to penicillins and other antibiotics.1 16 14
Spectinomycin is still useful against PPNG strains
but spectinomycin resistant PPNG strains have
already been reported in Korea19 20 and in other
countries,21 leading to fear that the days of
spectinomycin resistant N gonorrhoeae pre-
dominance might not be too far away. New reliable
treatment regimens therefore have to be sought.
Gentamicin, chloramphenicol, thiamphenicol, and traditional treatment regimens using penicillins and tetracyclines have been tried and found to be ineffective in Seoul. In previous publications we reported the sudden upsurge of PPNG strains among the isolates of N gonorrhoeae in 1981 and the continued high prevalence of PPNG strains thereafter in Seoul.

The strains of N gonorrhoeae isolated in South East Asia generally show low sensitivity to antibiotics. Korean strains show similar, if not lower, sensitivities to various antibiotics that have higher MICs for Korean strains than for those from Singapore reported by Sng et al. We compared our susceptibility test results with those of South East Asia and Singapore. The MIC of penicillin for our strains is considerably higher than for South East Asian strains; the MIC of tetracycline is slightly higher for our strains than South East Asian strains and even those from Singapore; and the MIC of spectinomycin is similar for strains from all three regions.

In previous work on the treatment of men with uncomplicated urethritis caused by PPNG we found that a single intramuscular injection of cefoperazone 0·5 g gave good results, with a failure rate of 0·8%. In this study we increased the dose to 1 g and found the effect to be excellent. All 42 cases were cured with a single injection of cefoperazone 1 g, and no side effects were detected. This suggests that cefoperazone 1 g by intramuscular injection is an excellent drug for the treatment of gonococcal urethritis caused by PPNG strains. A single injection of cefotaxime 1 g gave similar results, but required the concomitant use of 1 g probenecid, which might cause disturbances of the upper gastrointestinal tract.

In the face of increased resistance of N gonorrhoeae and high prevalence of PPNG strains among the isolates, especially PPNG strains resistant to spectinomycin, cefoperazone is an excellent alternative to spectinomycin in the treatment of urethritis caused by PPNG strains. The treatment is well tolerated and no side effects have been noted.
