The practice of STI treatment among chemists and druggists in Pokhara, Nepal

Chemists and druggists working in “medical shops” in Pokhara, Nepal, play a significant part in the treatment of sexually transmitted infections (STIs) in resource-poor countries. In some settings, chemists and druggists are consulted for first line treatment of STI symptoms more often than hospitals and clinics designed specifically to service such clients. Recent unpublished data from Pokhara, Nepal, suggests that in up to 80% of cases, treatment provided by chemists and druggists was inappropriate or incomplete. We report here on the quality of STI case management among a random sample of chemists and druggists in the 75 medical shops in Pokhara Municipality Area, Nepal.

Chemists and druggists working in all Pokhara medical shops, 65% of whom had received previous training in the national STI case management guidelines, based on WHO syndromic algorithms, were trained and motivated to initiate a register of all STI clients and their treatment. Registry data from January to December 1999 were reviewed. Thirty-seven registered medical shops were randomly selected for visits using the simulated client method (SCM) presenting 22 urethral discharge (UD) and 15 vaginal discharge (VD) scenarios.

Of the 6374 STI cases (68% female, 32% male), 22% presented with urethral discharge, 31% with vaginal discharge, 21% with genital ulcer disease, and 26% with pelvic inflammatory disease. Seventy per cent of chemists and druggists were made to feel welcome, given a private consultation, and were asked about their health history, risk counselling was conducted only 57% of the time, partner notification occurred in 43% of cases, and condom use was promoted in only 35% of cases.

Seventy per cent of clients visiting medical shops for STI treatment in Pokhara Municipality Area in 1999 came for first line treatment—findings in agreement with a recent study conducted in Ghana, which found that over 60% of STI clients came to pharmacies without a prescription. Although positive privacy and welcoming practices make medical shops a valuable outlet for STI treatment, only one quarter of chemists and druggists in Pokhara Municipality Area correctly dispensed medication for the treatment of UD or VD. While these data do not permit analysis of whether trained versus untrained providers were better at prescribing practices, it is clear that training efforts need to be expanded and intensified to improve STI control in this region.

Hepatitis, syphilis, and HIV sentinel surveillance in Mongolia 1999–2000

Mongolia has undergone healthcare modifications because of political changes resulting from the dissolution of the former Soviet Union. Dramatic increases in unemployment, alcoholism, commercial sex, homelessness, and sexually transmitted infections (STIs) have occurred. There has been rapid spread of HIV infection in neighbouring countries. Mongolia also has a high prevalence of hepatitis B. Although the Mongolian ministry of
health is eager to perform surveillance for STIs, including viral hepatitis, resources for collection, storage, and testing of specimens are meagre. We evaluated the utility of a filter paper blood collection technique for determining rates of HIV, syphilis, and viral hepatitis B and C in this resource limited setting. The study was approved by the institutional review boards at the University of Alabama at Birmingham and the Mongolian ministry of health. Volunteers including commercial sex workers, itinerant traders, homeless people, and attendees at the STI clinic were sampled in Ulaanbaatar, Mongolia. All subjects completed a questionnaire and provided blood via a finger stick.

Blood was collected as filter paper spot samples using Schleicher and Schuell (Keene, NH, USA) no. 903 filter paper following the National Committee for Clinical Laboratory Standards protocol. Samples were dried, stored at room temperature for the duration of the 2 week visit to Mongolia, and then refrigerated upon arrival to the laboratory. For every blood spot, a ¼ inch disc containing about 5 µl of serum was punched out of the filter paper. Disc samples were eluted in 400 µl of phosphate buffered saline for samples to be tested for HBsAg and HCVAb, 200 µl of specimen diluted solution for samples to be tested for HIV, or 100 µl of 10% PBS solution for rapid plasmin reagin (RPR) and FTA-ABS tests.

A total of 393 volunteers were enrolled. The prevalence of infection using the filter paper technique was 9.9% for syphilis, 10.5% for hepatitis C, and 21.6% for chronic hepatitis B. The prevalence of hepatitis C was higher among homeless people compared to other risk groups (21.3% vs 5.2–9.7%) (table 1). For 128 volunteers with chronic hepatitis B, 86 of them (67.2%) occurred in STI clinic attendees. Eleven individuals had reactive tests for syphilis. Three individuals had repetitively reactive ELISAs for HIV, however, none was confirmed by western blot. A total of 232 volunteers (39.1%) reported use of condoms routinely. 55/593 (9.2%) had a history of blood transfusion, and 9/593 (1.5%) reported use of injecting drugs. Neither condom use, number of sexual partners, nor a history of blood transfusion were predictors of hepatitis B infection. No correlations were found between the prevalence of hepatitis C virus infection and the use of drugs or history of blood transfusions.

We found the filter paper technique for blood collection to be a reliable and useful method for serological studies in resource poor areas where blood collection and/or specimen transport may be difficult. Specimens were easily collected, stored, and transported before testing. Rates of viral hepatitis were high but rates of syphilis and HIV unexpectedly low. Future prevalence testing using this method will be able to determine trends of these communicable diseases in Mongolia.

Congenital syphilis—missed opportunities for prenatal intervention

The changes in political, economic, and social life in the eastern European countries—that is, greater group mobility, substantial rise in travel activity, changes of the sexual behaviour are all related to the increased syphilis morbidity. The incidence of congenital syphilis morbidity in Bulgaria in 1999 compared with 1990—that is, 2628+378 diagnosed cases respectively, in 2000 there were 1605 cases. An increased number of syphilis patients among adults, and especially among pregnant women, reflected the growing incidence of congenital syphilis. The incidence of congenital syphilis in Bulgaria increased from one case in 1990 to 31 in 2000. This is observed as one of the most alarming trends in Bulgaria.

We report four infants with congenital syphilis—a 20 day old male infant, two male newborns, and a 2 month old female. The children were in quite a bad condition. They presented with disseminated papulovesicular rash (case 4), erythromasquamous and haemorrhagic (case 1), bullous and papulosquamous lesions, and prematurity (cases 2 and 3), thinning of hair, oedema of the hands and feet (in cases 1, 2, and 3), and hepatitis. Case 2 had asphyxia perinatalis, bradypnoea, bradycardia, atelectases pulmonum, hypothermia, respiratory acidosis with hypoxemia, and neurological symptoms. Osteonecrosis of the long bones on x ray was found in cases 1, 2, and 3. Patient 4 had pseudoparalytic arthropathy (the roentgenogram of the upper right extremity showed typical changes in the distal metaphysis of the humerus, and proximal metaphysis of the radius). Severe anaemia, leucocytosis, thrombocytopenia, elevated erythrocyte sedimentation rate, hypoalbuminaemia, hyponatraemia, elevated AST, ALAT, and LDH were noted in cases 1, 2, and 3. The TFS of patient 1 revealed features of vasculitis. The serological blood tests (VDRL, TPHA, IgG-FTA ABS) were positive, but CSF tests were negative. The children were treated with penicillin successfully. The mothers of the children had positive syphilis serology; they have not been treated for syphilis.

Congenital syphilis is a serious disease, whose clinical spectrum ranges from asymptomatic infection to fulminate sepsis or death. But many cases could be prevented with early and adequate prenatal care. Pregnant women are thus to be examined twice during pregnancy in the first and early third trimester as well as immediately after delivery (umbilical blood sample). Unfortunately, these rules are often not followed. The reduced or absent serological screening in pregnant mothers (as in our cases) is common. The mothers of cases 1 and 3 have not been tested at delivery. A general Lues serodiagnostic test is recommended in all newborns before they leave the obstetric departments.
Some authors found that the longest delay was the time at the laboratory as in case 1. (The mother was negative in the first trimester of pregnancy, became positive in the late third trimester, but the results came too late—after delivery.) Improved laboratory services will solve this problem.

Patients have often been treated by non-venerologists without contact tracing, like the father of case 1, and his diagnosis and therapy were not adequate. With regard to confidentiality patients often receive non-professional treatment or undergo self treatment.

Unfortunately, the difficulty in dealing with patients having a poor educational background and insufficient sexual knowledge results in the impossibility to find all the sources of infection. The parents of patient 2 did not seek medical help, although the father had penis lesion. The mother did not visit a doctor after she was pregnant. Even her labour was at home, as it was in the mother of case 4.

Another big problem is prostitution, which is not legal and cannot be controlled in our country. The mothers of patients 3 and 4 were prostitutes, who did not seek medical assistance at all.

More than half of our patients are unable to indicate the name or address of the contacts (the father of case 1 and the mothers of cases 2, 3, 4), thus demonstrating the high frequency of occasional sexual contacts and the lack of protective measures.

The government health system has existed in Bulgaria for more than 50 years but social and economic changes require a new insurance system and new approaches concerning STDs. The system for notification of STD cases also emphasises the necessity of cooperation between dermatologists, obstetricians, neonatologists, and paediatricians.

Condom access does not ensure condom use: you’ve got to be putting me on

Approximately 15 million incident cases of sexually transmitted infections (STIs) occur in the United States each year. These figures are troubling in light of primary prevention measures that sexually active people can use to avoid unprotected intercourse, including latex condoms. Although considerable attention has focused on making condoms widely available, surprisingly little research has examined whether condom availability is sufficient to ensure condom use. We recruited a convenience sample of 98 male students through advertisements posted in two university campuses to evaluate sexual risk taking behaviour. Men were required to be aged 18–29 years, full time students, and to have used condoms for ≥5 episodes of vaginal intercourse. After providing consent documents, “within the same room” (median 5 times; range 1–300). Overall, condoms, although readily accessible, were not used in more than one third (37%) of lifetime acts of intercourse where risk of pregnancy or infection was perceived (2254 acts). Reasons for men’s most recent failure to use condoms, despite accessibility, included unwillingness to interrupt foreplay (44%), fear of loss of sensation or erection (17%), and ineptitude (17%).

Among all 98 participants, 58 men (59%) also reported occasions in which they intended to use a condom, only to find that they did not have a condom with them. At the most recent occasion when condoms were not available, 34 men (58%) chose to have unprotected intercourse. The remaining 24 men (42%) abstained to interrupt foreplay (48%), fear of loss of sensation or erection (17%), and ineptitude (17%).

Resolution of the recent performance problem of Abbott LCx Chlamydia trachomatis assay. Issues of repeat testing for confirmation of chlamydial infection

In February 2001, Abbott Laboratories issued a device correction notice to users of their LCx Chlamydia trachomatis assay suggesting that initially reactive ligase chain reaction (LCR) tests should be repeated on the same sample to validate the test result. A recent alert (December, 2001) from the Medical Devices Agency (MDA, DA2001(09)) indicates that the device correction is still in force and points out the resource implications were retesting is required. We offer some data on LCR performance characteristics during this period and beyond.
The Department of Health pilot study on “Opportunistic screening for genital chlamydial infection in Portsmouth and Wirral” ran for a year up to October 2000. During that study, the standard adopted for reporting chlamydial infection included a repeat LCR test on all first catch urine samples that were initially LCR positive. Samples giving discrepant LCR results were further tested by Roche Cobas (PCR) polymerase chain reaction. Chlamydia LCR urine screening, with repeat LCR/PCR testing of positives, has continued in the Wirral pilot area and is also being used in other research projects locally.

Following the original device correction, we continued to carry out a repeat LCR but additionally included a PCR test on all initially positive LCR urine samples. Analysis of our data (table 1) suggests that compared to the Wirral pilot area and is also being used in other research projects locally.

The MDA alert properly deals with kit defects, and the Wirral Chlamydia Pilot (Sept 1999 to Oct 2000, baseline) and for 3 month periods since the issue of the device correction (February 2001). Table 1 Repeat LCR testing and PCR testing of initially positive LCR urines during the Wirral Chlamydia Pilot (Sept 1999 to Oct 2000, baseline) and for 3 month periods since the issue of the device correction (February 2001).
