Genital Chlamydia trachomatis remains year on year the most common sexually transmitted infection in the United Kingdom. In 1998 the chief medical officer’s expert advisory panel on chlamydia published its report, which concluded that testing should be offered to sexually active women under 25 years of age and to those over 25 years with two or more sexual partners within 12 months. The report also emphasised the importance of general practice in contact tracing and the need for collaboration between genitourinary medicine (GUM) and primary care. The report did not, however, make explicit the need for male practice in contact tracing and the need for collaboration between GUM and primary care.

While it is recognised that females often disproportionately bear the main burden of morbidity from chlamydial infection, it is often overlooked that chlamydia puts a heavy burden on male health causing epididymitis and infertility. The highest infection rates are currently documented in young women between 16–24 years of age, but as male testing is not pursued with the vigour of female testing are we really sure of infection levels in young males?

Although healthcare professionals’ awareness of chlamydia is rising, GUM clinics remain the only clinical setting that routinely test for chlamydia, yet it is estimated that only 10% of prevalent infection is diagnosed in GUM clinics. There remains a lack of availability of nucleic acid amplification tests (NAATs) and data on chlamydia testing practices and detection rates within primary care.

In view of this, improvement in detection, treatment, and management including contact tracing within sexual health services in primary care is desirable. This study was conducted following the piloting of a care pathway for chlamydia and the availability of a urine strand displacement assay (SDA, Beckton Dickinson, USA) in the 6 months before the research.

OBJECTIVES
To identify current levels of male testing and establish levels of knowledge relating to chlamydia infection among practice nurses in primary care in one north Wales local area health group (LHG) as part of a study to improve delivery of sexual health services in primary care.

METHOD
Study design
The questionnaire was designed to establish current levels of male testing and identify knowledge levels of chlamydial infection among practice nurses in primary care; it also aimed to elicit current practice including diagnostic tests being taken for male testing and indications prompting testing. The questionnaire was developed to suit the study and a draft questionnaire was piloted on four health professionals and amended according to feedback obtained.

Data from the questionnaire were summarised using frequency counts and percentages. When presenting the key results, it is important to show the effect that the relatively small sample size of this study may have had on these values. Therefore, 95% confidence intervals have been calculated for the key results.

Semistructured interviews were then undertaken with practice nurses who agreed to be interviewed with the aim of gaining further insight into the beliefs and knowledge base of the practice nurses.

Ethical approval was granted from North East Wales ethics committee (west, central, and east subcommittees). A research and development grant for costs to undertake the study was awarded by North East Wales NHS Trust.

Data collection
Data for the study were collected using a structured anonymous confidential self-completed postal questionnaire. For the purpose of the study, 46 individually addressed questionnaires were sent to all the practice nurses employed at 22 GP practices. Reminder letters were sent out 1 week later and reminder telephone calls made to all non-responders 1 week later. The questionnaires were anonymous.
and confidential, but a request was included in each letter for nurses who would be willing to take part in semistructured interviews as the second part of the study to provide their names and practice contact details. Data from returned questionnaires were analysed using the SPSS statistical package to establish concurring themes.

RESULTS
There was a 71.7% (33/46) response rate, with all 22 GP practices being represented. Seven nurses took part in semistructured interviews.

Responses to questionnaires
Examination of male genitalia was not carried out routinely by 30/33 (90.9%, 95% CI 76.4 to 96.9) practice nurses. Of the 18 nurses who responded to the question all indicated they were not performing urethral swabs for chlamydia on men. Urine SDA for detection of chlamydia had been used by 15/33 (45.5%, 95% CI 29.8 to 62.0) nurses.

In response to the question on when respondents would initiate chlamydia testing on a male patient, the five scenarios elicited consistent responses by one practice nurse 1/33 (3.0% 95% CI 0.5 to 15.3) who always initiated testing (table 1). No responses were obtained from approximately 60% of nurses. The indication that prompted most individuals to initiate chlamydia testing was that the patient’s partner had chlamydia, 11/33 (33.3%). Eleven out of 33 (33.3%) nurses stated that a male GP carried out chlamydia testing in their practice.

Referral of male patients with chlamydia to a GUM clinic was the routine practice of 20/33 (60.6%) nurses. Method of referral varied, 10/33 (30.3%) gave verbal advice only, while 23/33 (69.7%) nurses used two or more methods of referral including verbal, letter, and/or arranged clinic appointment by telephone on the patient’s behalf (table 1).

Contact tracing was not seen as part of the practice nurse’s role in delivering sexual health care by 28 (84.8%) practice nurses, three (9.1%) saw it as part of their role and two (6.1%) left the question blank. A number of nurses commented in the free text that they thought they did not have the time to become involved in contact tracing (box 1).

Respondents were asked what advice they give to a patient who has tested positive for chlamydia about recent sexual contacts, of which 29/33 (87.9%) nurses stated they advised that recent sexual contacts should be tested/treated. Twenty nine nurses do not offer to see sexual contacts even if they are from the same GP practice as the positive patients, four nurses do offer to see the contact. Patients were advised by 25/33 (75.8%) nurses to tell recent sexual contacts to attend a GUM clinic, but it still has a stigma

Semistructured interviews
Seven face to face interviews were carried out; none of the interviewees had ever taken a male urethral swab, but all were prepared to undertake the task if trained. Comments made suggested lack of confidence and knowledge on how to do urethral swabs was a significant factor in this (box 2).

The SDA chlamydia urine test had been used by 4/7 respondents, while all (100%) felt they would use the urine test if training was received on its use and four of seven felt it would be acceptable to men. All nurses stated that time was the main single factor that prevented them from partner notification. Training was highlighted specifically by two nurses and funding by one nurse to be an issue.

DISCUSSION
This study confirmed that there is a paucity of male chlamydia testing by practice nurses in primary care either opportunistic or on symptomatic males. Thirty (90.9%) practice nurses stated they do not examine male genitalia and 18 (54.5%) stated they never test males for chlamydia. These results mirror that of another study, which found that 67.5% of practice nurses never test males for chlamydia.6 Failure by nurses to identify the signs and symptoms of chlamydia in males represents lost opportunities to test and has implications for risk of complications developing and the

</table>
Results of this study have highlighted that 28 (84.8%) nurses do not consider contact tracing to be part of their role. Comments indicate that apart from lack of time to undertake contact tracing, lack of knowledge and training how to approach the issue was a barrier to carrying it out. Contact tracing for many in primary care is a daunting prospect, as partners may not be registered with the practice and to broach such a subject with a patient can be embarrassing for both health professional and patient; however it is economically effective.¹² The study demonstrates that practice nurses are only verbally advising an individual to attend a GUM clinic. These findings concur with a recent study of patients attending a GUM clinic that found 40.5% (39.9% had a sexually transmitted infection) of the patients seen had already been seen in primary care for their problem.¹³ It was found that duration of symptoms for those initially seeking treatment in primary care was substantially longer than for patients who attended GUM clinics directly. Facilitation of referral may be addressed by establishing care pathways.

This study, while small, demonstrates the urgent need to support practice nurses to carry out male testing in primary care. Currently, different levels of service and patient care for chlamydia are being provided to male patients within primary care.

Practice nurses require sexual health education and support in providing enhanced sexual health services. Development of care pathways, local training courses, and introduction of NAAT urine tests are recommended to improve the situation, and provide male patients with equity of care afforded to female patients. It is recognised that change is not spontaneous, but change is required within primary care in the form of the application of evidence based medicine/care to promote best practice and clinical effectiveness.
