sexual healthcare. Incapacitation cannot justify criminalisation in this case.

**Conclusion** Prosecution for non-intentional transmission of HIV through consensual sexual intercourse satisfies few of the justifications for punishment. The case for criminal sanctions should be reconsidered.

**LIFE-TIME AND RECENT RECREATIONAL DRUG USE IS MORE COMMON AMONG MEN WHO HAVE SEX WITH MEN COMPARED TO OTHERS ATTENDING SEXUAL HEALTH CLINICS**

doi:10.1136/sextrans-2012-050601c.179

P I Dargan, L Hunter, J A White,* A Benzie, D M Wood. Clinical Toxicology, Emergency Department and Sexual Health, Guy's and St Thomas' NHS Foundation Trust and King's Health Part, London, UK

**Background** Data on the frequency of recreational drug use (RDU) are collected at a population level through representative national surveys (eg, British Crime Survey). Anecdotally it appears that RDU is more common in men who have sex with men (MSM), but there are few systematic data to prove this. The aim of this study was to investigate the pattern of RDU in patients attending a sexual health clinic and to determine whether drug use was greater among MSM.

**Methods** We administered a questionnaire to all patients attending the sexual health clinics at two inner-city London teaching hospitals over a 3-month period (July 2011—September 2011). The questionnaire was self-completed by patients while waiting to see a clinician. Data were collected on age, gender, gender of sexual partner(s) and previous/current RDU (type and frequency of drugs used).

**Results** 1328 questionnaires were completed (mean±SD age 30.5±8.5 years, 54.9% female); 254 (19.1%) were MSM. Life-time use of all drugs, except cannabis, was more common in MSM; last-month use of most recreational drugs are more common in MSM and therefore interventions should be targeted to this population.

**VULVAL PATHOLOGY IN HIV POSITIVE WOMEN ATTENDING A TERTIARY VULVAL DERMATOLOGY CLINIC OVER A 5-YEAR PERIOD**

doi:10.1136/sextrans-2012-050601c.180

O Dosekun,* P Farrugia, F Lewis, G Sethi. Guy’s and St Thomas’ NHS Foundation Trust, London, UK

**Background** Studies have suggested that HIV infected women are at increased risk of developing invasive vulval carcinoma and recurrent herpes simplex type 2 (HSV-2) reactivation.

**Objective** To describe the spectrum of HIV associated vulval disease in women attending a tertiary dermatology referral centre in a busy urban setting.

**Methods** A retrospective case note review of all HIV positive women seen in the vulval dermatology clinic from January 2007 to January 2012.

**Results** 11 women were identified (see abstract P180 table 1). 9 (81%) were black Africans. The mean age at vulval disease diagnosis was 57 years. Most (81%) were already known to be HIV infected and on combined antiretroviral therapy (cART). There were six cases of undifferentiated vulval intra-epithelial neoplasia (uVIN) (45%) with two cases being diagnosed prior to an HIV diagnosis. The three cases of HSV-2 occurred in women with near-complete immune restoration on cART. Six women remain under regular dermatology follow-up, a median of 20 months since diagnosis.

**Abstract P180 Table 1** HIV positive women seen in vulval dermatology clinic 2007 to 2012

*At time of vulval diagnosis.

**Conclusion** There were no cases of invasive vulval carcinoma. HSV-2 may cause atypical disease even in the context of near-complete immune reconstitution on cART. Most women with vulval disease were already under HIV care, on cART and had a CD4 cell count above 200 cells/μl.
