SUMMARY From 26 April to 30 June 1983 a total of 200 men with uncomplicated gonococcal urethritis were randomly treated with either 2 g spectinomycin or 250 mg ceftriaxone, both administered intramuscularly. Of 197 isolates tested for the presence of the enzyme β lactamase, 91 (46·2%) were positive (PPNG) and 106 (53·8%) were non-PPNG strains. All 93 patients treated with spectinomycin and followed up and 97 treated with ceftriaxone and followed up were cured. Ceftriaxone 250 mg administered by intramuscular injection is highly effective in treating gonococcal infections caused by both PPNG and non-PPNG strains and is an appropriate alternative to spectinomycin.

Introduction

Ceftriaxone is a broad spectrum cephalosporin with an exceptionally long plasma elimination half life of about eight hours.1,2 It is the first long acting β lactam antibiotic. The aminothiazole methoxy-imino-acyl side chain gives the product good stability to β lactamase. The bioavailability of ceftriaxone after intramuscular administration is 100%. After injection, 60% of the drug is excreted in the urine and 40% is eliminated in the bile.3 Unlike many other cephalosporins, ceftriaxone is not excreted by tubular secretion. This is shown by the fact that probenecid has no effect on its elimination half life.4 It is a new third generation cephalosporin that has been found to be highly active against both PPNG and non-PPNG strains when compared with other cephalosporins of the same class.5,6 It is recommended for treating uncomplicated gonococcal infection in areas where PPNG strains are prevalent at a dose of 250 mg administered intramuscularly.7

The study reported here was undertaken to compare the efficacy of ceftriaxone and spectinomycin in treating uncomplicated gonococcal urethritis in men caused by both PPNG and non-PPNG strains.

Patients and methods

STUDY DESIGN We studied 200 Thai men who attended this hospital from 26 April to 30 June 1983 with uncomplicated gonococcal urethritis diagnosed by Gram stained smear microscopy at the initial visit to the clinic. They were randomly treated with either 2 g spectinomycin or 250 mg ceftriaxone, both administered by intramuscular injection.

DIAGNOSIS The diagnosis of gonorrhoea was based on the finding of Gram negative intracellular diplococci in Gram stained smears and on the results of cultures of material taken from the urethra. Blood was taken from each patient for routine serological tests for syphilis. The Gram stained smears were examined in the clinic; the other specimens were inoculated directly on to Thayer-Martin medium and incubated at 35°C in an atmosphere of carbon dioxide. Cultures were examined after 24 and 48 hours, and identification of Neisseria gonorrhoeae was based on typical colony morphology, a Gram stained smear showing Gram negative diplococci, and a positive oxidase test. Isolates were confirmed as being gonococci by sugar fermentation reactions. The colonies were subcultured to enumerate penicillinase producing strains of N gonorrhoeae by the cephalosporin test.8 The confirmed gonococcal isolates were later tested for sensitivity to antibiotics by an agar plate dilution technique.9

**Randomised comparative study of ceftriaxone and spectinomycin in gonorrhoea**

**FOLLOW UP**

Follow up visits were arranged on days 3, 7, and 14 after treatment. On each occasion urethral material was obtained for Gram smear microscopy and culture. Routine serological tests for syphilis were performed at monthly intervals for three months.

If gonococci persisted or reappeared within 14 days of treatment and the patient had not had further sexual intercourse, then the treatment was considered to have failed; the reappearance of gonococci after 14 days irrespective of the patient's history, was considered to be due to reinfection. Those who had had sexual exposure before the first follow up examination were excluded from the final assessment.

Postgonococcal urethritis (PGU) was diagnosed if Gram stained smears of urethral material showed more than 4 leucocytes per microscope field (× 1000) seven days after treatment.10

**STATISTICAL ANALYSIS**

The unpaired t test and the χ² test were used.

**Results**

Of 200 patients enrolled in the study, 10 were excluded; three because N gonorrhoeae could not be cultured, one because the patient had sexual intercourse before the first follow up, and six because the patients did not return for follow up examinations. Thus there were 93 patients treated with spectinomycin and 97 patients treated with ceftriaxone for evaluation. Table I shows the results of treatment; there were no failures in either group.

Of the 197 isolates with positive culture results tested for the presence of the enzyme β-lactamase, 91 (46·2%) were PPNG strains and 106 (53·8%) were non-PPNG strains.

**SENSITIVITY OF N GONORRHOEAE TO ANTIBIOTICS**

Table II shows the minimum inhibitory concentrations (MICs) of spectinomycin and ceftriaxone for the 196 isolates of N gonorrhoeae (91 PPNG, 105 non-PPNG) that were tested. The mean MIC of spectinomycin was 8·54 mg/l for PPNG strains and 8·12 mg/l for non-PPNG strains (t = 1·516; p>0·01). The mean MIC of ceftriaxone was 0·005 mg/l for PPNG strains and 0·004 mg/l for non-PPNG strains (t = 2·67; p<0·01).

PPNG = penicillinase producing N gonorrhoeae.

**SIDE EFFECTS**

No side effects to either drug were reported by the patients or noted on examination.

**POSTGONOCOCCAL URETHRITIS (PGU)**

Of 85 men treated with spectinomycin who attended for follow up on day 7 after treatment, 31 (36·5%) had PGU. Of 85 men treated with ceftriaxone who attended for follow up on day 7, 34 (40%) had developed PGU. The difference between the two groups was not significant (χ² = 0·225; p>0·01).

**Discussion**

In areas where β-lactamase producing gonococci are prevalent penicillin should not be used to treat gonococcal infections. Spectinomycin, cefoxitin, cefotaxime, and ceftriaxone have been recommended.7 Although there are reports from various parts of the world, including Thailand where PPNG strains are endemic, showing that spectinomycin, cefoxitin, and cefotaxime are effective in treating such infections, alternative treatments should be encouraged.11-18 Since 1981 PPNG strains resistant to spectinomycin have been reported.19,20

Ceftriaxone is a new third generation cephalosporin that has been found to be active against both PPNG and non-PPNG strains.5,6 In the study published here the non-PPNG strains were more susceptible than PPNG strains to ceftriaxone, a finding noted previously by Thabaut et al.6 The
treatment of uncomplicated gonococcal infection with 125-250 mg ceftriaxone in both men and women has shown 100% efficacy.21-26 Rajan et al also reported a cure rate of 100% in treating gonorrhoea with ceftriaxone 125 mg and probenecid 1 g.27 In our study we found that ceftriaxone at a dose of 250 mg administered intramuscularly without probenecid was highly effective for infections with both PPNG and non-PPNG strains. The patients tolerated the drug well and no one complained of pain at the site of injection. We conclude that ceftriaxone is an appropriate alternative to spectinomycin and other cephalosporins in treating gonorrhoea.

We thank the Roche Far East Research Foundation and Roche Thailand for providing the ceftriaxone used in this study.
