Sexually transmitted diseases in transient British forces in the tropics

E J Adams, P W Strike, A D Green, R G Masterton

Abstract

Objective—To compare the incidence of sexually transmitted diseases (STD) in British troops in the tropics with that in a standard population.

Design—Retrospective analysis of STD clinic records over one calendar year.

Setting—A British Military Hospital in the Tropics serving 1441 resident personnel.

Subjects—All patients attending a STD clinic.

Main Findings—815 cases of STD were recorded during the study period, giving incidence rate of 56 558 per 100 000 population per year. When compared with a matched population from England and Wales, the age standardised relative risk for STD amongst tropical troops was 25.0 (95% confidence interval 24.9 to 25.1). Thirty nine percent of cases reported prostitute contact as a source of their disease. Of patients questioned about condom usage, 70% reported that they did not normally use a condom.

Conclusions—British troops spending short periods of time in a tropical environment are significantly more likely to acquire a STD than men in the same age groups in England and Wales. The proportions of cases who reported that they did not use condoms and the number who cited prostitute contact as a source of infection indicate that even greater sexual education of troops on deployment overseas may be required.

(Genitourin Med 1994;70:94-96)

Introduction

Although military personnel have generally been regarded as a high risk group for sexually transmitted diseases (STD) a recent study in a stable European British Force showed a pattern and incidence of STD comparable to the civilian population of the United Kingdom.¹ We now report a companion study involving transient groups of British military personnel serving in a tropical environment.

Patients and methods

Records from a STD clinic at a British Military Hospital in a tropical area for a one year period were analysed retrospectively. The patients were drawn from a resident military

population of 1441 personnel, for which demographic details were obtained for the calendar year in which most of the study took place ("The Study Year").

The male England and Wales population in the study year was taken as the standard population for the purposes of comparison. The data for STD surveillance for the standard population were provided by the Public Health Laboratory Service Communicable Disease Surveillance Centre, and were taken from reports from genitourinary medicine Clinics for males in England and Wales aged 16 to 59 years in the study year. No information regarding the probable source of infection was available for the latter, so that in this instance only a comparison with 1983 figures¹ for British troops serving in Northern Europe was made.

For three months at the end of the study year a prospective investigation of condom usage was performed.

The age-standardized rate of STD in the military population was estimated using the indirect method described in detail by Armitage.² In simple terms the STD incidence of the study population was expressed relative to that of the standard population (males in England and Wales) by the ratio of observed to expected cases, which is termed here the standardised incidence ratio.

Results

Tables 1 and 2 respectively show comparisons between the composition and age distribution of the standard and study populations. STD cases are shown in table 3. Non-specific genital infection (NSGI) and gonorrhoea accounted for 45% of all cases.

The age standardised relative risk for STD amongst tropical troops was 25.0 (95% confidence interval 24.9 to 25.1).

Table 4 shows a comparison of the declared source of each case. Condom

Table 1 Comparison of the characteristics of the study and standard populations in the study year

	Study group (%)	England and Wales Population (%)
Proportion females	0.4	51.3
Proportion of males married	55.0	48.0
Proportion of personnel accompanied by spouse	6.0	Not applicable

Table 3 STD cases recorded in study population

	Study Group	
	No cases	Incidence rate 100 000/year
Syphilis	5	347
Gonorrhoea	128	8,883
Chancroid	28	1,943
LGV	4	278
NSGI	219	15,199
Candida	111	7,703
Pubic Lice	27	1,874
Herpes Simplex	22	1,527
Genital Warts	62	4,303
Other conditions requiring treatment	61	4,233
Other conditions not requiring treatment	148	10,271
Total STD	815	56,558

Study population n = 1,441.

Table 4 Sources of new cases of STD as a proportion of all new cases seen

	Prostitute	All others
Study group	39%	61%
European military population 1983(1)	8%	92%

Table 5 Condom usage of 140 consecutive male clinic attenders (three months at the end of study year)

	Used condom	No condom used
All sexual contacts	30%	70%
Prostitutes	31%	69%

Time of presentation of cases after arrival in tropics.

practices are reported in table 5. Figure 1 shows the time of presentation of cases from arrival in the tropics for patients with a known posting duration of 6 months.

Discussion

This study is qualified by its reliance on retrospective case record analysis which precludes standardisation or verification of diagnoses and case histories. However, the clinic was manned at all times by trained personnel and it was the only English speaking clinic to which patients had access. We therefore believe that a broadly accurate picture is given of the pattern and incidence of STD in the study population.

The earlier reports showing military personnel to be a high risk group for STD were based on studies of venereal diseases in male Service personnel during wars.³ The only study of British military forces in the tropics since 1945 looked at Army servicemen in Singapore in 1970 and showed syphilis to be fifty times commoner in that group than in UK males.⁴ Demographic details, including duration in the area, were not recorded. As neither of these studies involved age matched comparisons, no relative risk has previously been ascertained.

We have demonstrated that servicemen in the study group were 25 times more likely to acquire STD than men in England and Wales. This figure is broadly in agreement with the crude factor reported from Singapore. Schofield showed that STD amongst seamen is most commonly acquired in their home country rather than when travelling.⁵ Fulford *et al* found neither prolonged residence nor employment in the tropics to be associated with an increased risk of STD.⁶ Our findings are at variance with these reports which were based on clinic attenders in the United Kingdom.

The 1983 European study showed that the regular sexual partner was the commonest source of STD in servicemen. In that study prostitute-acquired disease mirrored reported UK data and was never greater than 11%.¹ However, prostitutes accounted for 65% of STD in combatant Australian troops in Vietnam⁷ and Thin commented on British Army patients in Singapore that “usually the primary contact was a local prostitute”.⁴ Although the pattern and spectrum of STD seen in the study and standard populations were broadly similar, certain notable exceptions predictably associated with tropical areas were found. These included lymphogranuloma venereum, chancroid and candidiasis. The much higher rate of STD observed in the study population suggests both an increased number of sexual encounters and an increased use of prostitutes. The latter was confirmed with prostitute-acquired disease running at approximately five times the rate in British forces stationed in Europe. These findings suggest that the sexual attitudes and behaviour of the study group, which is a cohort selected only by posting to a

tropical area, may be different from those of their counterparts in Europe.

This study did not specifically look for risk factors responsible for the observed rate of STD nor for indications of sexual activity. However, a number of potential influences were identified. The military population was almost exclusively male and "single" in the sense that a vast majority were separated from their regular partner for a significant period of time. The servicemen did not have ready access to the European women with whom they would normally form stable relationships. Finally, the age distribution of the study group was shifted from the standard population with the predominance of younger males possibly affecting the sexual behaviour of the group as a whole.

Given this study's results, the low condom use rate during sexual exposure is disappointing; particularly so is the finding that it was unaltered when the contact was a prostitute. This contrasts with studies in Edinburgh carried out in 1988 in which 62% of female prostitutes reported that they always used condoms.⁸ Health education lectures, includ-

ing STD briefings on risks and preventative action, form part of the arrival talks given to the study group. Figure 1, which shows increasing numbers of cases over the first months in the area, indicates that education should be reinforced at regular intervals.

We are grateful to the Director General of Medical Services, Royal Air Force, for permission to publish this paper and to Lieutenant Colonel Rao and Sergeant Stoker, without whose enthusiastic help this project would not have been possible.
