HIV tests in young adolescents attending a GUM clinic

A pretest counselling session is recommended by the General Medical Council before carrying out an HIV test and it is generally accepted that adolescents deemed competent enough to understand the counselling process can have an HIV test without parental consent. A recent survey in the United Kingdom showed that 79% of clinics were prepared to test for HIV infection in children under the age of 16. We reviewed the characteristics of adolescents between the ages of 13 and 16 seen in the Coventry genitourinary medicine (GUM) clinic for an HIV test between 1990 and 2000 (table 1). This was part of a larger review of GUM attendances by children, the results of which have been published.1

The commonest mode of presentation was a sexual transmitted infection diagnosed in eight girls (11.4%) versus two boys (16.7%); sexually transmitted infection diagnosed was associated with voluntary HIV testing. There was no statistically significant difference between those claiming rape/assault and those who were not in having an HIV test after counselling (95.2% versus 90.9%, p = 0.21).

There is no specific literature regarding the factors associated with HIV testing in young adolescents. A study of sexually active 16–19 year olds in Massachusetts found that infrequent condom use and a history of sexually transmitted disease were not significantly associated with voluntary HIV testing.2 Having had more than one sexual partner in the past year and discussing HIV/AIDS with a doctor were however associated with voluntary HIV testing.3

It has been shown that most adolescents engaging in high or moderate HIV risk behaviour continued to do so into young adulthood. Knowledge about HIV infection and its prevention, estimates of personal risk or exposure to HIV were not associated with change in behaviour.4 Effort must therefore be directed at research into adolescent risk behaviour change.

Sexual and reproductive health among female adolescents: preliminary results

The recognition of adolescence as an essential formative stage of life has implications for programming content and approaches. Young people have to be treated as people in their own right, and their individual needs considered on a case to case basis. The realisation that this is a time of significant opportunity and risk highlights the urgency to deal directly with sensitive topics such as sex and drugs.5

The aim of this study was to identify demographic, behavioural and clinical factors for STI and unplanned pregnancy among female adolescents assisted by the family health programme (PSF) of Vitória Municipality in Brazil. A cross sectional study was performed among female adolescents (15–19 years old) assisted by the PSF. Participants were screened for Chlamydia trachomatis and Neisseria gonorrhoeae using ligase chain reaction (LCR) applied to urine and answered a face to face questionnaire. Standard descriptive statistical analysis was performed. Prevalence rates were calculated to reflect the relative frequency of each disease with corresponding 95% confidence intervals (CI). The national school of public health (FIORUZ) ethics committee approved this study. Written, informed consent was obtained by all participants and their parents. The study included 149 adolescents. Mean age was 17.2 (SD 1.5) years; mean education was 8.3 (SD 2.9) years of schooling, and the mean age of the first sexual intercourse was 15.4 (SD 1.6) years. Seventy per cent of adolescents had already had sexual intercourse. Among those the prevalence rate of CT was 11.4% (95% CI 7.6 to 14), 4.0% (95% CI 2.1 to 5.2) of GC. Behaviour and clinical data are reported in table 1. There was statistical significance between chlamydia infection and previous STI (OR = 20.1, 95% CI 5.9 to 67.9); gonorrhoea and no condom use (OR = 1.2, 95% CI: 1.06 to 1.12) and gonorrhoea and alcohol abuse (OR = 1.3, 95% CI: 1.1 to 2.1). Clinical problems identified were genital ulcer 6.0%, dysuria 15.4%, inguinal lymphadenopathy 12.1%, vaginal bleeding 3.4%, and polyuria 2.7%.

STIs deserve attention not only because of their high prevalence but also because they frequently go undetected and untreated, and often result in serious sequelae and association with HIV infection.6 High prevalence rates associated with high frequency of risk were observed in this ongoing study. These two factors identify female adolescents as an important group to target with STI including HIV prevention efforts.

These data are descriptive and need to be completed but they are in agreement with the last research about Brazilian sexuality. It was reported that adolescents have their first intercourse earlier than the older generation and the knowledge about STI/AIDS does not modify the exposition.7 Eighteen percent of adolescents in Brazil become pregnant at least once and 54.1% among the married ones use some method of contraception.8 The preliminary results suggest that humane, healthcare based, STI/HIV prevention services in the health family programme can be an acceptable intervention, as well as one that is highly targeted epidemiologically. Screening, treatment and prevention counselling, and support in communities should be considered.

Factors affecting co-infection with genital chlamydia and genital gonorrhoea in an urban genitourinary medicine clinic

Co-treatment for chlamydia is common practice when gonorrhoea is diagnosed in a UK genitourinary medicine setting. In Glasgow, the incidence of gonorrhoea across the city has tripled from 1995 to 2000. Given this rise, we investigated whether our practice of co-treatment was of continued benefit. We examined all patients presenting to the Glasgow Royal Infirmary Genitourinary Medicine (GUM) Service (including the Steve Retson Project service for gay men) between 1 April 1997 and 30 September 2000 who had genital gonorrhoea diagnosed on routine culture. We diagnosed genital chlamydia co-infection by ligase chain reaction (LCR) on first pass urine (for men) or endocervical swab (for women). We diagnosed gonorrhoea in 351 attenders (287 men, 64 women), of whom 86 (25%; 95% CI 20% to 29%) were co-infected. Co-infection was significantly more common in women than men (29/64 (48%) vs .57/287 (20%; p = 0.02). Homosexual or bisexual men were significantly less likely to be co-infected than heterosexual men (15/134 (11.0%) v 42/153 (28%; p = 0.001). Co-infection became less common with increasing age (15–19 years 43%; 20–24 years 34%; > 24 years 18%; χ² for trend = 15.4; p < 0.0001) (see table w1 on STI website). Logistic regression modelling showed young age and female sex to be independent predictors of co-infection, while homo/bisexuality was protective (see table w2 on STI website).

We recommend continuing co-treatment for chlamydia in all women and heterosexual men presenting with gonorrhoea in our setting. However, in common with other recent findings co-infection with genital chlamydia is uncommon in male homosexual or bisexual attenders with genital gonorrhoea, and co-treatment may not be necessary in this group.

The data extraction was carried out by all authors and analysed by NL and CF. The article was drafted by all authors and all have approved the final draft. The authors declare that they have no conflict of interest in connection with this paper.

The completion of medical record reviews, the analysis, and drafting of this letter did not involve funding.
Four layer discontinuous gradient for HIV

Artificial insemination using processed semen is a risk reduction option, if they want children, for serodiscordant couples in whom the man is HIV positive. The main aim of this study was to develop a single semen processing technique to reduce HIV transmission risks to HIV negative wives without infection and to obtain better quality sperm.

Methods

After ethics committee approval and written informed consent, normozoospermic semen was provided by two asymptomatic HIV carriers. Discontinuous four layer density gradient, whose fractions (Fr) were 1.065 (Fr 4), 1.085 (Fr 3), 1.110 (Fr 2), and 1.135 (Fr 1), was prepared with Purep sperm. Washed with Hank’s solution was laid on this gradient and centrifuged at 400 g for 30 minutes. The specimen of each fraction was extracted to determine sperm quality and to detect HIV RNA and proviral DNA using RT-PCR and PCR, respectively. Lymphocytes of an HIV non-carrier were co-cultured for 4 weeks with each fraction. HIV proviral DNA using RT-PCR and PCR, respectively. Lymphocytes of an HIV non-carrier were co-cultured for 4 weeks with each fraction were determined by indirect immunofluorescence assay and cultivation with each fraction. HIV proviral DNA was not detected from Fr 2 or Fr 3 (tables 1 and 2).

Results

The percentage collection of sperm from Fr 1, Fr 2, Fr 3, and Fr 4 was 3% (SD 2%), 32% (9%), 19% (8%), and 10% (4%), respectively. Motility rate was 55% (19%), 94% (4%), 57% (25%), and 19% (11%), respectively. HIV proviral DNA and HIV RNA were detected only from Fr 4. HIV p24 antigen was observed in the lymphocytes co-cultivated with Fr 4 and from the positive control, but was not observed in other fractions. HIV proviral DNA was not detected from Fr 2 or Fr 3 (tables 1 and 2).

Discussion

HIV discordant couples have a risk of transmission generally if they wish to have a baby.1–5 Semprini et al reported continuous gradient centrifugation followed by a swim up procedure, and Marina et al carried out a similar method but HIV was detected in 5.6% of 107 samples. However, the condition of the sperm, after these processes, was not always sufficient for intrauterine insemination.

We have developed a novel semen single processing technique to reduce HIV RNA and HIV proviral DNA to undetectable levels in the fraction whose sperm motility was higher than others. Furthermore, this fraction was confirmed to have no HIV infectivity in vitro. This method appears to be an attractive alternative for HIV discordant couples.

Erythema nodosum induced by chancroid

Erythema nodosum is a panniculitic eruption which is often regarded as a complex reaction pattern to various aetiological factors of infective and non-infective origin.2–5 Infective agents outnummber inflammatory causes and drugs in causation of erythema nodosum in the developing countries. Almost all the infective agents including aerobic and anaerobic bacteria, viruses, fungi, parasites and mycobacteria can induce eruption of erythema nodosum.6 Among sexually transmitted infections lymphogranuloma venereum has been known to be associated with erythema nodosum not infrequently.7

A 23 year old woman presented with genital ulcer disease and painful rash over the legs of 1 week’s duration. There was no history of trauma, fever, or drug intake. She had a single stable extrater who was apparently unaffected. Examination revealed a single, 1–1.5 cm size, irregular tender ulcer on the right labia minora with undermined margins and bleeding on touch. The peripheral lymph nodes were firm, moderately enlarged, and tender. Speculum and vaginal examination was normal. Examination of the perianal region, perineum, and other mucosae was also normal.

Multiple tender, erythematous nodular subcutaneous lesions with dusky erythema were present over both shins, calves, and ankle joints. Investigations revealed a normal complete blood count, serum biochemistry, urinalysis and blood sugar. VDRL, HIV-1 ELISA, and HBsAg were negative. Dark ground illumination, smears, and cultures from the ulcer did not reveal aetiological diagnosis. Histopathology from the ulcer revealed an ulcerated surface with necrosis and neutrophilic infiltrate deeper to which a zone of new blood vessel formation with marked endothelial proliferation and a lymphoplasmacytic infiltrate was observed. This pathology was consistent with diagnosis of chancroid while histopathology of leg lesions confirmed it to be septal panniculitis consistent with a diagnosis of erythema nodosum. The ulcer was treated with erythromycin stearate 500 mg 6 hourly for 7 days. The genital ulcer healed completely in 7–10 days but the lesions of erythema nodosum subsided completely in 5–7 days without any other treatment.

Erythema nodosum as a cutaneous reaction pattern was first observed by Willan in 1798.8 A female preponderance with a ratio of 3:1 is often observed in adults compared to an equal incidence at prepubertal age. Although the exact pathogenesis of erythema nodosum is not known, it has been regarded as a immune complex, deposition disease which prefers the richly supplied vascular adipose tissue of the legs.

In the present patient, erythema nodosum and chancroid had a strong temporal correlation as erythema nodosum immediately followed the appearance of the chancroid and resolved completely with its resolution. Although erythema nodosum is known to be associated with innumerable infective agents, to the best of our knowledge chancroid leading to causation of erythema nodosum has not been observed before.

BOOK REVIEW

Not many books nowadays try to summarise the broad field of HIV and AIDS. This British Medical Bulletin does attempt to do that, in line with its usual approach to providing substantial coverage of health subjects, but with suitable depth as well as breadth. The last (and first) British Medical Bulletin on this subject was published in 1988. It covered quite similar topics, but the main change is the depth of knowledge.

Although the title of this volume reflects the general sense that the face of the pandemic has indeed changed in many ways—not least the global spread, and the impact of antiretroviral therapies where they are available—the overwhelming impression I had was how similar are the issues and perspectives it covers. This is partly a reflection of the extraordinary hothouse atmosphere of the early pioneering years, when we climbed the steep part of the learning curve with unparalleled speed. The subsequent years have been ones of consolidation, during which the detail has been explored and the basic ideas refined. This book reflects that, where the change in the face is in part a shift from an impressionistic image to a more fully representational portrait, evidently from the same original.

The chapters provide a balanced and compact, yet thorough, assessment of the main issues. The authors are active in the field; they have an appropriately British background for this series, yet their perspective is unequivocally global. The accounts are worthy, reliable, and authoritative. If this conveys the impression that they are rather dull to read, that was indeed my feeling. There was generally and disappointingly little sparkle or originality in the concepts or the writing. Where there was, it derived from a narrow focus on a small part of the canvas rather than any broader insight.

Who will use this volume? I would recommend it as a reliable and thorough review for a new entrant to the field. Those who work adjacent to it and who would like a compact, up to date summary would also be well served. Some of the chapters are an excellent springboard for detailed exploration of their topic. But those who already work on HIV/AIDS will find little to engage or excite them. They would probably feel, as I did, that the fascinating wider changes in the actual face of HIV/AIDS, which are palpable in their work, have scarcely been touched upon.
