If you have a burning desire to respond to a paper published in Sex Transm Infect, why not make use of our “eLetters” option?

Log on to the STI web site (www.stijournal.com), find the paper that interests you, click on [Abstract] or [Full text] and send your electronic response by clicking on “eLetters submit a response”.

Providing your letter isn’t libellous or obscene, it will be posted within seven days. You can view recent eLetters by clicking on “Read eLetters” on our homepage.

As before, the editors will decided whether to publish the eLetter in a future print issue.

Television coverage of AIDS and transmission of the AIDS virus

The introduction of the government framework “The national strategy for sexual health and HIV” is necessary for attempts to prevent sexual causes of premature death and ill health, at a time when transmission of HIV is at a record level and heterosexual intercourse is the most commonly reported mode of transmission. However, policy formation alone will not be effective in the fight against AIDS in the United Kingdom. Commentators have noted television coverage of AIDS has declined as the progression of the AIDS epidemic has fallen from media interest.

While television coverage raises AIDS awareness and encourages safer sex, it is unclear if it has an impact on infection rates. I have studied the association between television coverage and HIV transmission.

Television programmes with an AIDS specific content broadcast in the United Kingdom between 1981 and 2000 were identified. Criteria for inclusion were UK-wide terrestrial television programmes promoting AIDS awareness and encouraging the practice of safer sex; documenting the life of a person with AIDS; or a dramatisation featuring an AIDS storyline. Televised public education campaigns were excluded from the search, having been reported elsewhere. Television listings data were collected from a Scottish national newspaper (Daily Record) providing UK-wide television listings. Hand searching was conducted on the 1st, 15th, and 28th days of the months of February, May, August, and November, from 1981–2000: a 3.3% sample of available coverage. The sample was augmented by additional sources. A search for programmes shown as part of a one-off media campaign (as reported in the literature); between 27 February and 6 March 1987 to promote AIDS awareness and encourage safer sex was conducted. Supplementary programmes were obtained ad hoc from reviewing The Guardian CD Rom (from 1989–2000) and The End of Innocence: Britain in the time of AIDS.

Thirty seven UK terrestrial programmes covering HIV/AIDS were identified, the earliest in 1983, most recent in 2000, and a peak of programmes in the late 1980s. Between 1996 and 1999 no programmes covering HIV/AIDS were found. Twelve programmes about AIDS were shown during the media campaign of 1987. The decline in television coverage of AIDS contrasts with the steady increase in AIDS awareness and incidence of HIV transmission in the UK, 1981–2001.

A table of television coverage of AIDS 1981–2000 is on the STI website www.stijournal.com/

High frequency of antibodies to syphilis and HIV in hepatitis C virus positive blood donors may reflect its sexual transmission in this region

Hepatitis C virus (HCV) infection is a great cause of concern because of the risk of chronicity and other sequelae. Studies on the prevalence behaviour pattern and sexual transmission of HCV infection among the population are required for formulating strategies to control spread of HCV. The aim of this study was to evaluate the occurrence of HCV in voluntary blood donors as they are known to be a high risk population for transmission of these infections agents. Comparison was made between the presence of syphilis, HIV, and HCV infection in HCV negative and positive blood donors to confirm these as markers or predictors of HIV infection in a high risk population which may reflect the transmission of HCV by a sexual route.

Voluntary blood donors (n = 3905) from New Delhi, India, were randomly recruited between August 2001 to March 2002 and were unpaid. These donors were screened for antibodies to VDRL, hepatitis B surface antigen (HBsAg), hepatitis C virus (HCV), and HIV using previously validated second generation ELISA kits. Data were analysed using the \( \chi^2 \) test. Odds ratio (OR) was used to measure significance of association.
The antibodies to HCV were detected in 61 (1.56%), HbsAg in 109 (2.79%), VDRL in 132 (3.38%), and HIV in 40 (1.02%) donors. In HCV negative blood donors, VDRL was detected in 129 (3.35%), HbsAg in 106 (2.75%) and HIV in 31 (0.8%) donors, while in HCV positive blood donors HIV positivity increased significantly to nine (14.75%) OR (21.2) and VDRL and HbsAg reactivity was found 21.2, 1.48, and 1.82 times more respectively in HCV positive blood donors (table 1).

In conclusion, the high frequency of antibodies to syphilis and HIV in HCV positive blood donors may confirm this as a marker or predictor of HIV infection in a high risk population and may also reflect the risk of transmission of HCV by the sexual route, which seems to vary with the population studied.

Self obtained samples for genitourinary infections
We assessed the concept of self sampling, as part of screening for sexually transmitted diseases, first in the early 1990s in a pilot study. The aim was to assess the validity and acceptability of the procedure as an alternative for the sex industry workers (or as a supplementary method between attendances), for those who are reluctant or unable to attend GUM care (between visits) in special patient groups, for those who are sexually abstinent or engaged in care (between visits) in special patient groups, for those who are sexually abstinent or engaged in

and the attempt to take the swabs from the cervical surface. In our study, 86.7% of patients reported their ability to access the cervix (and, therefore, obtain high vaginal/cervical samples). The squatting position has the advantage of providing patients with the freedom to use both hands (one of which may be used to open the vulval lips). The technique is similar to that employed by women for self examination before the insertion of a cervical or for obtaining a VDRL or the intrauterine contraceptive device threads.

The new methods of information technology, with their declining cost, can provide extra support to the concept of self obtained samples with quick and easy access to their results. The result of the tests may then be obtained by the patient by telephone (possibly via an automated service or a text message, using an identifier number). The procedure is already in use by the banking services for accessing personal and confidential information. It is possible to provide the sampling materials in a “test pack” that may be returned to a central laboratory, by post. The pack may include information and explanatory notes and a coded identification number. This would help to identify the patient’s samples, with confidentiality.

The recent escalation in the incidence of sexually transmitted infections, coupled with the increasing workload for GUM clinics is representing a challenge for adopting new ways in combatting the spread of sexually transmitted infections. The exploitation of new ideas, methods, and technologies could be of benefit, especially in areas out of access to advanced laboratory investigations (remote and rural areas). It could also be used as a supplementary method to current medical care (between visits) in special patient groups (for example, adolescents’ and sex industry workers’).

A survey of STI policies and programmes in Europe
The survey by Dehne et al was carried out in 1998–9 and inevitably does not necessarily represent the current situation. The authors report that the United Kingdom has no national STI programme and management guidelines. The first ever national strategy for sexual health and HIV for England was published in 2001. It contains the two key objectives of ensuring that everyone has better access to information on sexual health and to make services more available and accessible to all those who require them at all ages. The strategy also has specific aims of reducing acquisition, transmission, and the prevalence of undiagnosed HIV and STIs. Specific targets to increase the uptake of HIV testing in hepatitis B vaccination have also been set. The issue of case management guidelines was not detailed in the strategy since this has been specifically tackled by the specialty of genitourinary medicine. A clinical effectiveness group was set up between the Association of Genitourinary Medicine and the Medical Society for the Study of Venereal Diseases in 1997, with the specific remit of producing evidence based national guidelines and standards for those working in the specialty of genitourinary medicine. These were published in STI in 1999 and updated in 2002.

I hope these observations will help to update the survey with particular reference to England.

Polymorphic immune restoration syndrome after effective HAART
HAART is able to suppress HIV replication and restore specific immune responses. We and others have demonstrated that previously

Accepted for publication 30 October 2002

www.stijournal.com
untreatable progressive multifocal leucoencephalopathy (PML) may improve and has very rarely been reported following HAART. However, CD4+ increase is also associated with inflammatory reactions to previously silent infectious agents, as well as aberrant immune phenomena.\(^1\)

**Case report**

A 27 year old HIV/HCV (hepatitis C virus) patient was observed in 1997 with a CD4+ count of 357 cells ×10³/l. HAART was started and maintained until 1999 when it was stopped at the patient’s request. On October 2001 he returned asymptomatic, with a CD4+ cell count of 34 ×10³/l and HIV-RNA 130 000 copies/ml. Stavudine + lamivudine + nevirapine were then started, together with trimethoprim-sulfamethoxazole. He experienced an optimal response (CD4+ count 159 ×10³/l, HIV-RNA <30 copies/ml on March 2002). One month later, the patient was admitted because of mental slowness, aphasia, ataxia, impairment of fine movements of the right arm, and hypopnea of the right leg. He was afebrile and laboratory tests showed WBC 5300 ×10³/l, RBC 4550 ×10³/l, Hb 16.1 g/dl, PLT: 259 ×10³/l, eosinophils 8.3%, AST 369 IU/l, ALT 1446 IU/l, γ-GT 599 IU/l, PT 84%, and raised total plasma IgE 330 IU/ml. Toxoplasma serology, HbsAg, HbsAb, and HAV-IgM were negative; and HCV-RNA was positive; a cidofovir standard dose was initiated. HAART was observed (fig 1) and PML stabilised. Subsequently, progressive improvement was observed (fig 1) and PML stabilised.

**Comment**

We report a complex polymorphic immune restoration syndrome of PML (demonstrated also by JCV-PCR in contrast with previous reports\(^2\)) combined with the first case of liver damage related to delayed immune mediated hypersensitivity reaction to nevirapine. Several facts support an immunophagogenetic role of aberrant immune recovery in this case: (i) these phenomena occurred together in concomitance with raising CD4+ T cell count under effective HAART; (ii) PML during HAART is exceptional; (iii) both PML during HAART\(^2\) and nevirapine hypersensitivity\(^3\) occurred during the first weeks of therapy in the case series reported so far; (iv) nevirapine hypersensitivity is frequent in conditions of hypersensitivity is frequent in conditions of delayed immune mediated restoration syndrome of PML (demonstrated also by JCV-PCR in contrast with previous reports). Therefore, it would have been very difficult to make the correct differential diagnosis with either late onset metabolic idiosyncrasy to nevirapine or relapsing HCV hepatitis without liver histology. Thus, avoiding liver biopsy in such cases may lead to an understimation of the causative role of nevirapine.
