A comprehensive systematic review of HIV and risk behaviour studies in Lebanon was undertaken. Sources of data included (1) PubMed using a strategy with both free text and MeSH headings, (2) country-level reports and databases including governmental and non-governmental organisations publications, and (3) international organisations reports and databases.

Available data indicate that HIV prevalence among the high risk groups ranged between 0 and 3.6% among men with sex with men (MSM), 0 and 5.9% among injecting drug users (IDUs), and 0%–0.3% among female sex workers (FSWs). HIV prevalence in the general population was very limited (~0%). Analysis of HIV notified cases indicated a substantial recent increase in the contribution of male same-sex sex, whereby 52% of notified cases in 2008 were due to MSM transmission compared to 13% in the cumulative period until 2008. Substantial levels of risk behaviour were reported by the three high-risk groups. MSM reported an average of 9.5 sexual partners in the last year and up to 36% engaged in male sex work. Seventeen to 65% of IDUs shared needles/syringes, 53%–47% had sex with FSWs, 17%–53% engaged in sex work, and 24.7% reported male same-sex sex. FSWs reported an average of 11.7 sexual partners per week. Despite relatively high levels of risk behaviour, condom use in Lebanon was high and among the highest in the MENA region, so were the levels of knowledge of HIV/AIDS and of its modes of transmission. Molecular epidemiology evidence indicated a diverse HIV subtype distribution suggesting multiple exogenous introductions of the virus.

The evidence gathered in this review indicates that HIV endemic transmission appears to be still limited in Lebanon with most diagnosed cases representing exogenous exposures. There are however few indications suggesting an emerging epidemic among MSM. HIV surveillance of high-risk groups needs to be actively expanded in Lebanon to track such potential emerging epidemics and prevent further HIV transmission among population groups at high risk of HIV infection.

Conclusions The evidence gathered in this review indicates that HIV endemic transmission appears to be still limited in Lebanon with most diagnosed cases representing exogenous exposures. There are however few indications suggesting an emerging epidemic among MSM. HIV surveillance of high-risk groups needs to be actively expanded in Lebanon to track such potential emerging epidemics and prevent further HIV transmission among population groups at high risk of HIV infection.

Methods A comprehensive systematic review of all HIV-1 molecular epidemiology data in MENA was undertaken. Sources of data included (1) PubMed using a strategy with both free text and MeSH headings, (2) country-level reports and database including governmental and non-governmental organisations publications, and (3) international organisations reports and databases.

Results In several countries such as in Lebanon, Saudi Arabia, and Yemen, a very diverse distribution of HIV-1 subtypes was observed reflecting principally travel-related exogenous exposures. A trend of a dominant HIV-1 subtype was observed in few other settings and was often linked to HIV transmission within specific high-risk core groups such as subtype A and CRF55_AD among IDUs in Afghanistan, Iran, and Pakistan; and subtype C in heterosexual commercial sex networks in Djibouti and Somalia. Subtype B was predominant in Northern Algeria, Tunisia, and Morocco, but this appeared to reflect a mix of indigenous endemic transmission and exogenous exposures of West European and North American origin.

Conclusions Multiple introductions of HIV-1 variants due to exogenous exposures of nationials seemed common to all MENA countries, as observed from the high diversity in subtypes or the high genetic divergence among any specific subtype even if predominant. This is in part a reflection of the high population mobility in MENA. In several countries though, epidemic-type clustering of specific subtypes suggests established or nascent HIV epidemics among classical core risk groups for HIV infection. With overall weak surveillance systems in MENA, molecular investigations could help identify the emergence of hidden epidemics among high-risk groups. HIV prevention efforts in MENA must be prioritised for these groups.
