7–49 days). In 16% of patients time to enter care took over 150 days; those infected by heterosexual contact or injecting drug use were more likely to be in this group. Patients born outside the Netherlands were also more likely to enter care late. 2) From February 2009 until April 2010, 120 participants were included in the study (response 70%). The majority (n=108) were men who have sex with men (MSM). For 78% of participants a date of entry into care was known; median time into care was 8 days (range 0–104 days). Twenty two per cent had not entered care yet of whom 16% had CD4 cell counts below 350. Of participants who were directly referred to an HIV treatment 10% delayed for medical care compared to 45% of participants wanted to make an appointment on their own initiative.

**Conclusions** Specific subpopulations such as heterosexuals and ethnic minorities are at risk for entering care late after being diagnosed HIV positive. Results from the prospective study show that direct referral from STI clinic to an HIV treatment centre leads to less delay. Testing of those at risk is not enough to interrupt HIV transmission chains, entry into care needs to be assured as well.

**05-S2.03 EFFECT OF IMPROVING THE STI SERVICES IN SEVEN PROVINCES OF CHINA**

X D Gong, J Jiang, X h Su, N X Cao, X L Yue. Institute of Dermatology, Chinese Academy of Medical Sciences, National Center for STD Control, Nanjing, China

**Background** The STI services can reduce HIV transmission and have been the important component of HIV control programmes. In China, the STI services remain weak. Under the framework of AIDS control programme of the Global Funds Round 4, we conducted the sub-programme to improve STI services in 21 counties of 7 provinces in China from 2007 to 2009, including one-week training workshops for all STI care providers, two-month field training for key STI clinicians at STD Clinic of National Center for STD Control, STI drug assurance, and quality services offering for STI patients. Annually the effect of STI services was assessed according to the guideline of WHO/UNAIDS in the 21 counties.

**Methods** The assessment of STI services was through health facility survey, including three indicators: (1)STI service indicator 1 (SSI) is defined as the per cent of patients with STIs at observed health care facilities who are appropriately diagnosed and treated according to the national guidelines on STI treatment in China; (2) STI service indicator 2 (SI2) is defined as the per cent of patients with STIs who are given advice on condom use and partner notification and referral for HIV testing in term of national standards; (3) Standardised STI service indicator (SSI) means the comprehensive case management including SI1 and SI2. The sample size of STI patients between service indicator (SSI) means the comprehensive case management including SI1 and SI2. The sample size of STI patients between 100% of public and 66% of private providers. Most clinicians were nurses (91%), female (89%), from public clinics (92%), and had formal STI (87%) or HIV (96%) training within 10 years. The median number of STI patients seen daily was 6 and most providers were experienced in STI care (median 9.5 years), although more so in private clinics (11.7 years). Most clinicians recognised most of the common syndromes and correctly identified treatment options, particularly for bacterial genital ulcer syndrome. Most (94%) understood genital herpes recurs, but only 85% agreed herpes could be treated. Nonetheless, misperceptions were common: less than half (48%) agreed with the statement that some STIs cannot be cured with medication,” only 5% disagreed that “herpes is curable,” 54% agreed “untreated STIs develop into AIDS,” and 33% agreed that “HIV medications were more dangerous than having AIDS.” STI or HIV training was either unrelated or inversely related to these misperceptions. While most providers (95%) felt offering HIV testing to STI patients was one of their most important responsibilities, many (27%) believed it permissible to test patients for HIV without consent. Clinicians reporting having STI or HIV training were more likely to agree with HIV testing without consent (30% vs 17%, p=0.001) see Abstract O5-S2.04 table 1.

**Conclusions** Most clinicians understood STI syndromic treatment, however many misunderstood important aspects of HIV/STI clinical care and their implications for prevention. Brief refresher courses on specific aspects of treatment and prevention may benefit HIV/STI clinical care and prevention in Gauteng.
