Background Our service is located in a high HIV prevalence area (6.2/1000), and a large proportion of late presentations. We have widened the availability of HIV testing as a major strategy to reduce HIV related morbidity and mortality in our population.

Aims/Objectives To assess the evolving trends in demographics, clinical and laboratory findings of newly diagnosed HIV patients in our busy inner city clinic. To develop HIV testing strategies further with the implementation of current NICE guidance that recommends testing all medical admissions, and assess the potential future impact of this on presentation patterns in our cohort.

Methods Retrospective case note review of 92 consecutive new HIV diagnoses between 2009 and 2011. Data were collected on demographics, clinical stage, CD4 count, source of referrals, and drug resistance. Findings were compared to previous data sets in the same clinic over three audit periods between 2005 and 2011.

Results The proportion of males newly diagnosed has increased from 53% (2003) to 51% (2011), and the median age of all diagnoses has crept up to 39.5 years from 36.7 years. The proportion of referrals from primary care is now the largest (51%). Very late presenters (CD4 <200), remain high in our population at 53%, and this is well above the national average of 50%. Primary drug resistance is 16%, currently double the national average.

Discussion/Conclusions There continues to be a high rate of very late presenters in our cohort. Strengthening current interventions and implementation of NICE guidance will be essential in an effort to reduce late diagnoses.

Discussion Diagnosing and treating HIV infection early is an important way to slow down the spread of the epidemic and targeting those at greatest risk should be a priority. However, despite migrant-focussed awareness campaigns, migrant workers and their partners are not accessing testing and treatment until they become sick. The cultural preference for private treatment, the insecurity of migrant work and gender differences in health-seeking behaviour delay early diagnosis and treatment initiation.

Background BHIVA published guidelines in 2008 on the treatment of HIV infected adults. These guidelines were used as a basis for optimal patient care.

Aims To audit the following against BHIVA guidelines: (1) Initial investigations, assessment and monitoring after diagnosis (2) Choice of first line ARV regimen (3) Attainment of target HIV viral load <50 by 6 months of treatment (4) G.P. involvement in patient care.

Methods The medical records of 24 HIV positive patients, who were diagnosed and started on ARV medication during the preceding 12 months, were reviewed.

Results Initial investigations and assessment were done in all patients (100%), with the exception of cardiovascular risk assessment which was documented in only 20% of patients. 18/24 patients (75%) were started on the first line regimen recommended [2NRTI and 1 NNRTI], out of which 14 patients (58.3%) were started on Atripla. 5 patients (20.8%) received [2NRTI and boosted PI] and one patient was on [2NRTI and integrase inhibitor]. 20 patients (83.3%) achieved the target VL <50 within 6 months of treatment. In 5/24 (12.5%) patients the viral load was still detectable at 6 months. One patient moved away from the region. The G.P. was informed about the HIV positive status in only 62.5% patients.

Conclusion Several areas of clinical practice were identified for improvement and the following actions recommended: the use of a web-based virtual clinic resource which includes links to CVS risk calculators; proactive discussion with patients regarding the importance of disclosure of HIV status to their GP for safe and efficient care.

Background Our ARV Network’s 2009 audit highlighted the large proportion of patients with a CD4 count <500. A re-audit was designed to provide more information on patients with CD4 counts in this range.

Methods We conducted a retrospective review of case notes for all patients in the network starting ARVs in 2010. For analysis of CD4 counts the cohort was divided into two groups; those diagnosed within 1 year of starting treatment and others.

Results 114 patients started ARVs in 2010 from four centres in our network. 62 (54.4%) were male. Mean age was 38.4 years (range...

FOUR YEARS OF POST EXPOSURE PROPHYLAXIS FOLLOWING SEXUAL ASSAULT (PEPSE) PRESCRIBING AFTER SEXUAL ASSAULT IN A SEXUAL ASSAULT REFERRAL CENTRE (SARC)

R MacDonald,* 1T Groom, 2D Wardle. 1Sandyford Initiative, Glasgow, UK; 2Sandyford Initiative/Archway, Glasgow, UK

Aim We have reviewed 4 years of PEPSE use in our SARC and its follow-up and compared with BASHH guidance on PEPSE after sexual assault.

Methods Retrospective review of SARC and GUM notes from 12 October 2007 to 12 October 2011

Results 1233 cases seen 127 given PEPSE, for two notes not available. Age range 14–55 years mean 27. 81% were female. 51% were Asian, 4 Dark European, 13 unknown. One man had PEPSE twice. Mean time till received PEPSE was 25 h range 3–72 h or low risk exposures. 87 returned at day 3 for review. 29 stopped PEPSE early.

Discussion A proportion of our cohort started ARVs with a low CD4 count mainly due to late diagnosis. This is an important barrier to ARV initiation and needs to be addressed and our audit data would support the need for extra support and resources directed to earlier HIV diagnosis.

POST EXPOSURE PROPHYLAXIS FOLLOWING POSSIBLE EXPOSURE TO HIV INFECTION: AN EVALUATION OF 391 ATTENDANCES AT THREE CENTRAL LONDON SEXUAL HEALTH CLINICS

Background Providing post exposure prophylaxis (PEP) following possible HIV exposure is a common GU presentation. However, few studies have evaluated this practice.

Aim(s)/Objective(s) To answer the following on PEP presentations: age, sex, nature of exposure to HIV, time to presentation for PEP, side effects, completion rates, presence of sexually transmitted infections (STIs), appropriateness of PEP dispensing and comparisons of findings with other published studies.

Methods GUM clinic attendances were evaluated from April 2009 to March 2010.

Results There were 391 PEP attendances: 375 males (96% MSM), 18 females. Age range 19–87 (mean 35.4) years. Presentation followed anal sex in 89%, vaginal sex in 5%. The remainder attended following oral sex, splash incidents, injecting drug use, or other exposure. Forty six percent attended within 24 h, in one instance PEP was dispensed beyond 72 h. The majority completed PEP (92%). Side effects were experienced by 60%. Baseline screening for hepatitis B showed active infection in 1% and immunity in 74%. A baseline HIV test was conducted in all but one patient. An STI screen was conducted at or around day 14 in 69% of patients, with 12% testing positive for an STI in line with previously published data. Follow-up rate at 3–6 months was 52%. Of 203 patients tested for HIV at follow-up, 2 (1%) tested positive.

Conclusions PEP was dispensed appropriately in the majority of cases. The fact that 82% of individuals completed treatment despite side effects is likely to be due to the use of more tolerable regimens than were used historically. The presence of an STI in 12% of people tested highlights the importance of screening in individuals presenting for PEP. The fact that only 52% of patients attended for a follow-up HIV test at 3–6 months is of concern and warrants further exploration.

WHAT'S UP? ERECTILE DYSFUNCTION (ED) IN HIV POSITIVE MEN

A Williams,* S Dharmaratne, B T Goh. Royal London Hospital, London, UK

Background Antiretroviral therapy in HIV positive patients has resulted in improvements in survival, quality of life and fulfilling sexual relationships. Treatment using phosphodiesterase type 5 inhibitors (PDE5i) for ED has simplified management. However nitrates, including “poppers”, and protease inhibitors (PIs) can interact with PDE5i leading to hypotension and high levels of PDE5i. Ethical issues are a consideration as treatments can lead to HIV transmission if safer sex is not practised. We reviewed our HIV positive men with ED and their outcomes after treatment.

Methods 94 HIV positive patients attending our ED clinics from 2006 to 2012 were identified. Data were collected by review of notes and databases. Patients on PIs were started on half of the lowest risks after exposure and hopefully make it easier to discuss this with the client.
