The National Institute of Health and Welfare, Oulu, Universities of Oulu, Tampere and Helsinki, Finland.

We studied *C. trachomatis* (CT) serotype-specific antibodies in Finnish women between 1980’s and 2000’s. *C. trachomatis* seropositive women (1,169) were available from a subcohort (11,067) of the Finnish Maternity Cohort representing the 1980’s (N = 480) and 2000’s (N = 331) for serotype specific classification by microimmunofluorescence test. Serotype distributions were comparable in the 1980’s and 2000’s, G, E and J being the most prevalent. Serotype D peaked in the 1990’s. The overall serotype profile changed first between 1980’s and 1990’s but changed back in the 2000’s. The rates of women with antibodies against two or more serotypes increased in the 1990’s, but then decreased again. In conclusion, we analysed the rates and distributions of CT serotype-specific antibodies from the 1980’s to 2000’s in fertile-aged female population in Finland. We found that CT serotype distributions varied considerably over time.

**P2.141** KNOWLEDGE, ATTITUDES AND PRACTICES OF HEALTHCARE WORKERS FROM UNIVERSITY HOSPITAL OF OUAGADOUGOU (BURKINA FASO) FACE TO ACCIDENTAL BLOOD EXPOSURE (ABE) AND BIOLOGICAL FLUIDS IN CARING IN FACILITIES

Y Sagna, S Kouanda, H Tiéno, R A K Nianogo, R Bogounou, J Y Drabo, Internal Medicine Department of Yalgado Ouédraogo University Hospital (CHU YO), Ouagadougou, Burkina Faso; Institut de recherche en sciences de la santé, Ouagadougou, Burkina Faso

**Objective** Accidental blood exposure (ABE) is defined as “any accidental exposure to blood or to a biological fluid contaminated by blood, including a cutaneous injury during an incision or injection, or a projection on mucosa or on an injured skin”, we aimed to evaluate the knowledge, attitudes and practises of healthcare workers in one of West Africa country national referral hospital (Yalgado Ouédraogo University Hospital) face to ABE.

**Methods** A descriptive cross-sectional and analytical study was conducted, from May to July 2009, on all healthcare workers (medical, paramedical and support staff) working for at least a year in this hospital university. A self and anonymous questionnaire was used to gather the information. The knowledge assessment was made using a digital scale.

**Results** 462 healthcare workers responded to the questionnaire (response rate: 51.3%). They composed of 60 physicians (12.9%), 313 paramedics (67.7%) and 89 support officers (19.2%). The exact definition of an ABE was known from 255 healthcare workers (55.2%) and 375 (81.2%) were aware of the principles of universal precautions. Medical staff better defined the ABE than the other healthcare workers (p = 0.00). 153 healthcare workers (29.4%) were at least once a victim of an ABE, of which 84 (61.3%) had not reported their ABE. Ignorance of the support procedures was in 26.8% of cases the main cause of no report. The risk of contamination after ABE had not been assessed in 60.3% of cases. Only 69.7% of the healthcare workers were aware that HIV is a potentially transmissible infectious agent during an ABE. Protective equipment was not always available and not constantly used.

**Conclusion** The ABE knowledge of these referred hospital health-care workers is not satisfactory. Appropriate communication and awareness means on the risks associated with the ABE should be further developed in healthcare settings.

**P2.142** TOO BAD! SINGLE MOLECULE ANTIRETROVIRAL DRUGS MAY NOT BE THE MAGIC BULLET

T Agarko-Poku, Adu Sarkodie. Suntreso Government Hospital, Ghana Health Services, Kumasi, Ghana; School of Medical Sciences, Kwame Nkrumah University of Science and Technology, Kumasi, Ghana

**Background** Adherence to Antiretroviral drugs (ARVs) poses a challenge for an effective Antiretroviral Therapy in Ghana. The introduction of single molecule ARVs regime was seen as an antidote to non-adherence among HIV patients on treatment. This study was conducted among ARVs experienced patients, who were about to be switched onto single molecules, to determine their perception on the new treatment regime.

**Methods** 1681 HIV positive patients from Suntreso STI/HIV Clinic in Kumasi, who have been on treatment for more than 12 months and consented to participate in this cross sectional study, were interviewed using structured pretested questionnaire prior to the commencement of the new single molecule ARVs treatment regime. Data was entered and analysed using SPSS version 16.

**Results** Whereas 60.9% (1023/1681) find the present dose regime cumbersome, 39.1% (657/1681) prefer the multiple dose regime. 42.2% (709) of respondents have some reservations about single dose regime whilst 24.6% (413) prefer it with 33.3%(559) being indifferent. Reasons for the reservation included; ‘Side effect may be too serious’ (48.3%, 342/709), ‘Virus too powerful for a single molecule’ (50.2%, 214/709), ‘Attempts to deprive us of drugs and facilitate our death’ (15.8%, 92/709) and ‘Cost of drugs will be expensive in future for a combine drugs’ (7.7%, 55/709).

**Conclusion** Although majority of patients find the multiple dose regimes cumbersome, they are sceptical about the use of the single molecule regime. The new regime may result in overdosing if they find it inadequate to provide the needed protection. The fear of serious adverse reaction from combination of ARVs compared with separate drugs, may scare them from taking the treatment. Intensive adherence counselling taking care of the above concerns is essential before patients are switch onto the single molecule ARV regime.
Conclusion

We propose that with good interagency and MDT working, an efficient and effective ART delivery service is feasible, with patient and hospital benefits. Collaborative approaches between the delivery service and HIV MDT should be established and regularly evaluated with patient input. Identifying a key contact person for the delivery service is important to ensure continuity of communication, together with a local contractual service level agreement to ensure clear terms of reference and accountability. Results of a qualitative patient survey evaluating the delivery service are imminent.

Background

In 2011, 1.3 million sexual health screens (SHS) were conducted in genitourinary medicine clinics across the UK, a doubling of workload in the last 8 years. One approach UK clinicians have adopted in managing this increase is for minimally trained non-medical staff (health care support workers (HCSWs)) to deliver protocol driven asymptomatic screening to low risk patients. There is limited research regarding patient confidence with the service offered by HCSWs and re-attendance rates could be an indicator of patient dissatisfaction.

Aim

To assess whether patients who have asymptomatic screening with HCSWs were more likely to return for subsequent assessment by a clinician following discharge.

Method

A case controlled study of 300 asymptomatic patients attending for sexual health screening between October 2011 and April 2012. There were 2 arms with equal patient numbers, the HCSW led clinic and the clinician led clinic. Data collection and analysis for both groups included patient demographics, diagnoses, treatment, test results and time to next new diagnosis.

Results

No significant difference was found between the patient demographics of the two groups. The rates of Chlamydia infection between the HCSW and the clinician groups were 8% and 7.3% respectively. Within the clinician group 4 cases of syphilis, 1 new diagnosis of HIV and 1 case of Hepatitis C were also diagnosed. The HCSW clinic had 19 (12.7%) patients re-attend for further screening within 11 months compared to 16 (10.7%) patients who saw a clinician, showing no significant difference between the two groups [p = 0.124 Fishers exact test]. Only 1 patient from each group re-attended within 6 weeks for further screening due to the development of symptoms.

Conclusion

This study highlights low patient re-attendance rates within the HCSW group. This is an indirect marker of patient satisfaction and demonstrates patients are reassured with the service they offer.

Background

The BRAVO trial is an ongoing study designed to determine whether bi-monthly home-screening and treatment for asymptomatic bacterial vaginosis (BV) reduces risk of urogenital chlamydia and gonorrhoea infections in young women. Return rate of self-collected swabs is a critical element of home testing interventions. We conducted this preliminary analysis to determine the swab return rate and to assess its association with age, race, or recruitment setting.

Methods

Participants, recruited from 10 clinics in 5 cities, were asked to mail self-collected vaginal swabs to the research team every 2 months for one year. For each evaluable participant, we determined the number of kits returned (of 6 total) and compared the proportion of women that returned all 6 kits according to age, race, and recruitment setting.

Results

Data were available for 756 participants who were primarily non-Hispanic Blacks (76%), with median age 21 (range: 17–25 years), and mostly recruited from STD clinics (82%). Nearly all women (89%) returned at least one swab; 59% returned all 6 kits; 14% returned 5, 16% returned 1–4, and 11% returned none. Complete swab return rate (all 6) was greater among women aged 23–25 than those aged 17–22 (67% vs. 56%, p < 0.01) and varied among the 5 recruitment cities (range 42%–66%, p = 0.02). Return rates were not significantly associated with race and Hispanic ethnicity, or with recruitment from STD clinics vs. other settings (58% vs. 66%, p = 0.10).

Conclusions

The majority of study participants submitted all six home-screening kits, and 73% completed at least five. Adolescent women aged 22 and younger had a lower return rate than women aged 23–25, although the complete return rate was still over 50%. Therefore, frequent home-screening for BV and STIs is feasible in clinical trial settings and could likely be implemented as part of clinical care and STD prevention programmes.
