(63.4%) men who have sex with men only; 34 (8.2%) men who have sex with both men and women. Among the women: 74 (73.3%) African-American; 18 (17.8%) White; 6 (5.9%) women who have sex with women only; 8 (7.9%) women who have sex with men and women. Among men, the prevalence of CT was 10.7% (2.7% throat, 5.8% rectal and 3.4% urine); for GC 8.5% (6.5% throat, 3.4% rectal and 1.2% urine). Among women, the prevalence of CT 12.9% (4.9% throat, 8.9% rectal and 8.9% urine); GC 3.0% (1.0% throat, 3.0% rectal and 1.0% urine). 95.9% of the individuals reported high acceptance of self-testing with 97.6% willing to do repeat testing and 96.7% to recommend self-testing to someone else.

**Conclusion** HIV-negative, asymptomatic adults testing for HIV are infected with other STIs. Self-testing for CT and GC was implemented successfully among men and women. Self-testing can mitigate HIV infection by increasing detection and treatment of STIs amongst those seeking HIV testing only.

**Methods** On a monthly base, physicians reported aggregated STI testing data. Individual data was provided for each positive patient including demographics, re- and co-infections and assumed risk behaviour. Via patient questionnaires, information on socio-demographics, way of transmission and sexual behaviour was collected. All questionnaires were sent via regional to coordinating partners for merging and analysis.

**Results** Overall, 467797 tests were performed in 45 sentinel sites (Austria 13, Slovakia 14, Romania 15, Bulgaria 5). The countries varied in the number of STI tests (range: 6071 – 298645), positivity rate (range: 2–13%), patient characteristics and sexual behaviour: 75% of all women with an STI in Austria were sexworkers, compared to 5% and 8% in Bulgaria and Romania. 34% of all men with an STI in Slovakia had sex with men, compared to 4% in Romania. STI patients, especially women had a migration background in 79% in Austria, but less than 7% in the other three countries. Casual partners were the presumed cause of infection in the majority of MSM in all countries, whereas condom use in the last 6 months with these partners varied significantly between the 4 countries.

**Conclusions** Although not representative, sentinel surveillance gathers useful information on groups most at risk and can be compared between countries when using the same instruments. Legal and social issues can hinder disclosure of sexual preferences and practices and hamper targeted prevention. Enhancement of condom use with casual partners in MSM seems to be crucial, particularly in the East.

**P3.184** **SEXUALLY TRANSMITTED INFECTIONS AND PREGNANCY OUTCOMES, FLORIDA 2008–2010**

**Background** A prior population based study found the odds of low birth weight for women with inadequate weight and history of Chlamydia trachomatis (CT) infection during the pregnancy was nearly twice that of women without CT infection (AOR 1.98, p < 0.02). A stronger association was observed with pre-term low birth weight (AOR 2.34, p < 0.01). Subsequently, 2005–2006 ratified state laws and regulations required Ct screening during pregnancy.

**Objectives** To examine associations between Ct infections during pregnancy and birth outcomes among women who gave birth in Florida after implementation of mandated Ct testing.

**Methods** Logistic Regression analysis of Florida birth records (548,407) linked to records for women who tested positive for Ct (12,334), were treated and gave birth from 01/01/2008 to 12/31/2010.

**Results** Among 18–35 years old, with singleton births, 2.7% were reported with chlamydia during pregnancy and 6.5% experienced low birth weight (LBW) outcome, less than 2500 grammes. After controlling for smoking, prenatal care, race, education, marital status, inadequate weight gain and nine other covariates, Ct infection treatment in gestation weeks 17 through 28 was associated with increased odds of delivering a moderately LBW infant (1500 to 2499 grammes) (AOR 1.29, 95% CI 1.12 to 1.49). No association was found for very LBW infants (< 1500 grammes) or for Ct infections treated before 17 weeks gestation. The increased odds for moderately LBW were observed for preterm (< 37 weeks gestation) moderately LBW infants (AOR 1.28, 95% CI 1.07 to 1.53) and term (≥ 37 weeks gestation) moderately LBW infants (AOR 1.27, 95% CI 1.03 to 1.57).

**Conclusions** Proactive public health policies for chlamydia screening during pregnancy and intensified treatment timeliness may have contributed to improved pregnancy outcomes, but Ct infection continues to be associated with increased odds of moderately LBW. Prospective examination of treatment dosage and timeliness may prove informative.

**P3.185** **CHLAMYDIA TRACHOMATIS IN THE GENITAL TRACT OF HIV-INFECTED WOMEN, PREGNANT AND NON-PREGNANT, FOLLOWED IN A REFERENCE CENTRE IN BAHIA, NORTHEAST BRAZIL**

A. A. A. Travassos, I. Nóbrega, E. Netto, M. Timbó, K. Adami, S. Fernandes, P. Silva, M. Pires, C. Queiroz, C. Brites, Centro Estadual de Diagnóstico, Assistência e Pós-Pacientes (CEDAP-SEASAB), Salvador, Brazil; Universidade Federal da Bahia, Salvador, Brazil

**Background** Genital tract infection by Chlamydia trachomatis (CT) is associated with complications such as pelvic pain, infertility and ectopic pregnancy, besides increased risk of HIV sexual transmission. Its occurrence during gestation worsens perinatal morbidity and mortality. In HIV-infected pregnant women also increases the risk of HIV mother-to-child transmission despite the use of HAART. In Brazil, there are few data on the prevalence of HIV/CT co-infection and associated risk factors.

**Methods** Cross-sectional study of HIV-infected women attending in a reference outpatient clinic for gynaecology and prenatal care between October 2010 and September 2011 was conducted, evaluating laboratory and clinical data. The search of CT was performed using Hybrid Capture II collected from endocervix, and clinical data were obtained from standard questionnaire and survey data in medical records.
Results 112 HIV-infected women were enrolled, of whom 52 non-pregnant and 60 pregnant. In this population, mean age was 32.3 years (SD = 8.2). 62.5% had a previous history of sexually transmitted diseases, 46.4% began sex life with 15 years or less, 33.1% reported having less than 5 sexual partners throughout life, 45.8% had undetectable HIV viral load. We found a prevalence of 5.4% of Chlamydia trachomatis infection in HIV-infected women followed. There was an association of CT with the presence of pregnancy (10.0% versus 0.0%; p = 0.019), HIV viral load > 10,000 copies (p < 0.001) and the mean time of HIV diagnosis (21.0 versus 69.2 months; p = 0.032). We found no association with other risk factors studied (ethnicity, marital status, education, use of alcohol and drugs, CD4+ T Lymphocyte count).

Conclusion Early access to diagnosis and treatment of infection by HIV and Chlamydia trachomatis is an important preventive action. In pregnant women infected with HIV, the prevalence of Chlamydia appears to be greater and this is a period where treatment can improve maternal and neonatal outcome.

Background Little is known on the natural history of extragenital Chlamydia trachomatis (Ct) and Neisseria gonorrhoeae (Ng). More insight in the natural history of extragenital Ct and Ng could influence standard operating procedures in screening facilities such as STD clinics. We evaluated proportions of natural clearance of Ct and Ng in genital and extragenital samples.

Methods We included self collected Ct and/or Ng positive genital (urine and cervicovaginal) and extragenital (anorectal and oropharyngeal) samples from STD clinic attendees [April 2011-December 2012]. Data on demographics and sexual behaviour were collected in an electronic patient file at initial testing. At follow-up for treatment, subjects were retested prior to treatment at the same anatomic site(s) as initial testing and provided an additional questionnaire on sexual behaviour since initial testing. Natural clearance rates of Ct and Ng were compared between anatomic sites. Data on the first 238 individuals (299 samples) are presented, enrollment is ongoing.

Results In total, 38% of the participants were male and the median age was 27 years. The median interval between initial and follow-up sample was 11 days. Natural clearance of Ct was 10.5% (22/210) for genital samples (36% urine, 64% vaginal) and 25.9% (7/27) for extragenital samples (57% anorectal, 43% oropharyngeal) (P = 0.49). For Ng this was 22.2% (2/9) for genital samples (0% urine, 100% vaginal) and 18.8% (3/16) for extragenital samples (35% anorectal, 67% oropharyngeal) (P = 0.84). Overall, natural clearance of Ct was 12.2% (29/237) and Ng was 20.0% (5/25) (P = 0.14). Age < 25 years (P < 0.01) and female sex (P = 0.03) were associated with overall Ct clearance. Median interval was not associated with Ct/Ng clearance (P = 0.13 and P = 0.11 respectively).

Discussion Natural clearance of Ct and Ng was substantial in both genital and extragenital samples. Further analysis on associated determinants as well as bacterial load determinations will provide more insight into these results.

Background Cytomegalovirus (CMV) is one of the commonest viral opportunistic infections in persons with Acquired Immune Deficiency Syndrome (AIDS). In AIDS patients, progressive loss of immune function, and in particular, loss of cell mediated immunity, permits CMV reactivation and replication. This study aimed to evaluate the prevalence of seropositivity for CMV IgG and IgM among HIV sero-positive patients in Ilorin, Nigeria

Methodology Sera obtained from 180 HIV sero-positive individuals and 180 HIV sero-negative blood donors participants were assayed for CMV IgG/IgM using Enzyme Linked Immunosorbent Assay (ELISA). The CD4 cell counts were also done. A semi-structured questionnaire was used to obtain information on the risk factors for CMV/HIV co-infection.

Result A total of 169(99.9%) of the HIV sero-positive were CMV IgG positive while, 174(96.7%) of the control were also CMV IgG positive. Among the HIV sero-positive, 20 (11.1%) were CMV IgM antibody positive, while 4(2.2%) of the HIV sero-negative control group were CMV IgM positive. Age of Participants (p = 0.000), number of sexual partners(p = 0.000) and CD4 cell counts(p = 0.000) were significantly related to CMV IgM sero-positivity. However the use of HAART (p = 0.777), history of blood transfusion(p = 0.837)
