0.49 (0.30–0.80), p = 0.004, respectively), while those with a concurrent STI [1.69 (1.15–2.49), p = 0.007], and those presenting with multiple infection sites [2.54 (1.62–4.00), p < 0.001] were more likely to be culture-confirmed.

**Conclusion** Not all NAAT-positive attendees were culture-confirmed, but this may be because culture was either unsuccessful or not routinely performed among asymptomatic attendees. All NAAT-positive patients should be cultured before treatment, as routine culture confirmation is essential to ensure representative monitoring of trends in antimicrobial resistance to inform decisions regarding treatment guidelines for gonorrhoea.

**P3.285** DIAGNOSTIC AND TREATMENT UNCERTAINTIES: EPIDEMIOLOGICAL RISK FACTORS FOR NAAT POSITIVE BUT CULTURE NEGATIVE GONORRHOEA CASES IN STOCKHOLM, SWEDEN

R Vyth, A Leval, B Eriksson, M Hergens. Dept. of Communicable Disease Control and Prevention, Stockholm County, Stockholm, Sweden

**Background** The advent of gene amplification testing methods for Neisseria gonorrhoeae has lead to a higher prevalence of gonorrhoea testing in the population. Various methods for Nucleic Acid Amplification Tests (NAAT) are used, often with high specificity. The sensitivity of culture is substantially lower than NAAT. Before diagnostic and treatment accuracy for gonorrhoea, the objective of this study was to examine epidemiological risk-factors for NAAT positive but culture negative cases.

**Methods** The study included all men and women in Stockholm having at least one positive gonorrhoea NAAT test with follow-up cultures taken during the period January 1, 2011–June 30, 2012. The total number of eligible cases during this period was 938. Data on sex, age, mode of transmission, symptoms, Chlamydia trachomatis co-infection and NAAT lab method were collected. Outcome was defined as positive NAAT but negative follow-up culture. Descriptive statistics and cross-tabulations with chi-squared tests were performed.

**Results** In total, 19% of NAAT positive cases had no positive cultures (N = 174). Diagnostic certainty was greater among men than women. Ten-percent of men and 37% of women with positive NAAT had negative cultures. Three laboratory NAAT methods were used with differences in subsequent negative culture proportions found among these methods.

**Conclusion** Women have an increased risk for incorrect diagnosis and/or treatment of gonorrhoea. Improved gonorrhoea testing practices are necessary to avoid systematic misdiagnoses and inappropriate treatments.

**P3.287** COMPARISON OF ANTIMICROBIAL SUSCEPTIBILITY OF NEISSERIA GONORRHOEAE ISOLATES OBTAINED FROM THE PHARYNX, RECTUM AND URETHRA IN MEN WHO HAVE SEX WITH MEN

1 S Kidd, 1 L Asbel, 1 T Baldwin, 6 G Grater, 1 R Kerani, 1 P Pathela, 1 K Pettus, 1 O O Soge, 1 A Stirland, 1H Weinstock. 1Centers for Disease Control and Prevention, Atlanta, GA, United States; 6Philadelphia Department of Public Health, Philadelphia, PA, United States; 2Texas Department of State Health Services, Laboratory Services Section, Austin, TX, United States; 3Howard Brown Health Center, Chicago, IL, United States; 4University of Washington and Public Health – Seattle and King County, Seattle, WA, United States; 5New York City Department of Health and Mental Hygiene, New York City, NY, United States; 6Neisseria Reference Laboratory, Harborview Medical Center, Seattle, WA, United States; 7Los Angeles County Department of Public Health, Los Angeles, CA, United States

**Background** Gonorrhoea is the most prevalent bacterial sexually transmitted infection globally. It is of grave concern that Neisseria gonorrhoeae has developed resistance to many antibiotics introduced for treatment. China is located in the WHO Western Pacific Region (WPR), where most gonococcal antimicrobial resistance (AMR) has originated. However, the information regarding AMR and particularly molecular epidemiology of N. gonorrhoeae strains in China is highly limited. This study investigated the AMR and molecular epidemiologic clusters of N. gonorrhoeae in 2007 and 2012 in Nanjing, China.

**Methods** A total of 204 and 82 N. gonorrhoeae isolates were collected in 2007 and 2012, respectively, in Nanjing, China. The
susceptibility to ceftriaxone, spectinomycin, ciprofloxacin and tetracycline were tested using agar dilution method, according to the recommendations from CLSI. NG-MAST was performed for molecular epidemiology and full-length PCR sequences were used for phylogenetic analysis.

Results All (100%) isolates were resistant to ciprofloxacin, tetracycline, and 41.6% produced β-lactamase. According to the CLSI breakpoints, all (100%) isolates were susceptible to spectinomycin (S ≤ 32 µg/ml) and 99.7% to ceftriaxone (S ≤ 0.25 µg/ml). However, using the European breakpoints 5.2% of the isolates were resistant to ceftriaxone (EUCAST; S ≤ 0.125 µg/ml). The most prevalent NG-MAST clusters in 2007 included ST568 (n = 15), ST270 (n = 9), ST421 (n = 7), and ST2288 (n = 5). The most prevalent clusters in 2012 included ST1055 (n = 4), ST2318 (n = 4), ST5990 (n = 4), and ST1614 (n = 4). Isolates with identical or phylogenetically similar STs had similar MICs of ceftriaxone. Many novel STs were identified.

Conclusion Ceftriaxone and spectinomycin can continuously be recommended for treatment of gonorrhoea in Nanjing, China. The different molecular epidemiologic clusters in 2007 and 2012 indicate fluctuations in the sexual networks in Nanjing. The identified correlations between NG-MAST STs and MICs of antimicrobials suggest that NG-MAST can supplement the AMR surveillance in China, which needs to be further strengthened.

**P3.289** MIC CREEP TO CEFTRIAXONE AND LOW LEVELS OF RESISTANCE TO AZITHROMYCIN IN 7 COUNTRIES FROM SOUTH AMERICA AND THE CARIBBEAN

The Gonococcal Antimicrobial Susceptibility Program (GASP) Network in Latin America&Caribbean, 1P Araaya, 2G Borthagaya, 2P Galaza, 3A Llop, 4D Payares, 4G M Sanabria, 4S D Thakur, 4M E Trigoso, 4J R Dillon, 1Instituto de Salud Publica de Chile, Santiago, Chile; 2Facultad de Ciencias, Universidad de la Republica, Montevideo, Uruguay; 3Centro Nacional de Referencia en ITS INEI-ANLIS “Dr Carlos Malbran”, Buenos Aires, Argentina; 4Instituto de Medicina Tropical “Pedro Kouri”, Ministerio de Vigilancia, Informacion y Referencia, CDVIR, La Paz, Bolivia, Plurinational State of; 5Centro Nacional de Referencia en ITS INEI-ANLIS “Dr Carlos Malbran”, Buenos Aires, Argentina; 6Instituto de Medicina Tropical “Pedro Kouri”, Ministerio de Vigilancia, Informacion y Referencia, CDVIR, La Paz, Bolivia, Plurinational State of; 7University of Saskatchewan, Saskatoon, SK, Canada; 8Centro Continental de Vigilancia, Informacion y Referencia, CDVIR, La Paz, Bolivia, Plurinational State of; 9University of Saskatchewan, Saskatoon, SK, Canada

Background The World Health Organization (WHO) issued an international action plan in 2012 to mitigate the health impact of antimicrobial resistant Nisseria gonorrhoeae isolates. A key strategy is to strengthen international surveillance of gonococcal antimicrobial susceptibility. The Gonococcal Antimicrobial Surveillance Program (GASP) in Latin America and Caribbean (LAC) has reported on AMR trends from 1990. The present study presents regional trends in antimicrobial susceptibility between 2010 and 2011.

Methods Seven countries reported using either agar dilution (CLSI), Etest or disc diffusion assays to determine antimicrobial susceptibility. Countries were asked to report MIC data and categories of susceptibility.

Results Seven countries tested 1019 isolates of N. gonorrhoeae in 2010 and 1216 isolates in 2011 to ceftriaxone, penicillin, tetracycline and ciprofloxacin (n = 7); azithromycin (n = 4) and spectinomycin (n = 3). Several countries reported a 2-fold increase in MICs of ceftriaxone (from 0.004 to 0.008 µg/ml) between 2010 and 2011 and 12 isolates with ceftriaxone MICs 0.125–0.25 µg/ml were reported in 2011. All isolates were susceptible to spectinomycin. Resistance to azithromycin increased slightly from 1.0% (6/612) to 1.7% (20/1169) while resistance to ciprofloxacin decreased from 42.1% (429/1019) to 36.2% (439/1214) of isolates tested between 2010 and 2011. Resistance to penicillin increased from 31% (310/1016) in 2010 to 38% (428/1216) in 2011 while the percentage of isolates resistant to tetracycline was stable (2010–2011: 21.8%, 187/858; 2011–2012: 22.6%, 275/1216).

Conclusions Three generation cephalosporins and spectinomycin continue to be viable options for the treatment of gonorrhoea in the countries reporting. Low percentages of resistance to azithromycin continue to be reported. There has been a steady decline in capacity for N. gonorrhoeae diagnosis and antimicrobial susceptibility testing in the region. The implementation of the WHO action plan to control the spread and impact of antimicrobial resistance in N. gonorrhoeae is an urgent priority.

**P3.290** HIGH RATES OF CHLAMYDIA POSITIVITY IN ABORIGINAL AND TORRES STRAIT ISLANDER PEOPLE ATTENDING AUSTRALIAN SEXUAL HEALTH SERVICES: THE AUSTRALIAN COLLABORATION FOR CHLAMYDIA ENHANCED SENTINEL SURVEILLANCE (ACCESS)

1,2,3,4C C O’Connor, 1H Ali, 1R Guy, 4C K Fairley, 4M Y Chen, 4J Marshall, 4J Kaldor, 4M Hellard, 4B Donovan, 1,4J Ward, 4Kirby Institute, The University of New South W, Australia; 4RPA Sexual Health, Sydney Local Health District, Sydney, Australia; 4Central Clinical School, Sydney University, Sydney, Australia; 4School of Population Health, University of Melbourne, Melbourne, Australia; 4Melbourne Sexual Health Centre, Melbourne, Australia; 4Fremantle Hospital, Fremantle, Australia; 4Centre for Population Health, Macfarlane Burnett Institute for Medical Research and Public Health, Melbourne, Australia; 4Sydney Sexual Health Centre, Sydney Hospital, Sydney, Australia; 5Baker Institute, Alice Springs, Australia

Introduction Australia has a widely dispersed network of public sexual health services that see large numbers of people at risk of genital Chlamydia trachomatis infection. ACCESS was established to monitor chlamydia testing and positivity rates nationally and to assist the interpretation of chlamydia diagnoses reported through passive surveillance. We report on chlamydia testing and positivity in Aboriginal and Torres Strait Islander (hereafter Aboriginal) people attending 18 sexual health services participating in ACCESS between 2006 and 2011.

Methods Using line-listed data, we analysed Aboriginal status reporting, testing rates based on first visits and chlamydia positivity in those tested. Outcomes were stratified by age group, sex, and year of attendance and were compared with non-Indigenous clients using a chi-square test and multivariate logistic regression (p < 0.05).

Results From 2006 to 2011, 7,103 (4.2%) Aboriginal people and 161,626 (95.8%) non-Indigenous people attended participating sexual health services that see large numbers of people at risk of Chlamydia positivity in Aboriginal and Torres Strait Islander females and non-Indigenous males and females between 2006 and 2011 (p-trend < 0.01). On multivariate analysis, positivity was associated with younger age, being heterosexual and living in Queensland in both Aboriginal men and women. In addition, in Aboriginal men, positivity was associated with not living in a remote area, and not having sex overseas; and in Aboriginal women, it was associated with attending in 2010 or 2011.

Conclusion The high Chlamydia positivity rates and increases over time highlight the need for enhanced prevention and screening programmes in Aboriginal people in Australia.

**P3.291** ASSOCIATIONS OF CHLAMYDIA TRACHOMATIS INFECTION IN MEN AND WOMEN WITH GENITAL DISCHARGE SYNDROMES IN JOHANNESBURG, SOUTH AFRICA

F Radebe, 1C Rickelty, V Kekana, A Vezi, 1Basson, P Magooa, N Bhraj-Sewpershad, G de Gita, V Masako, D A Lewis, 1National Institute for Communicable Diseases (NICL), Sandringham, South Africa

Introduction Chlamydia trachomatis is a common sexually transmitted infection. ACCESS was established to monitor chlamydia testing and positivity rates nationally and to assist the interpretation of chlamydia diagnoses reported through passive surveillance. We report on chlamydia testing and positivity in Aboriginal and Torres Strait Islander (hereafter Aboriginal) people attending 18 sexual health services participating in ACCESS between 2006 and 2011.

Methods Using line-listed data, we analysed Aboriginal status reporting, testing rates based on first visits and chlamydia positivity in those tested. Outcomes were stratified by age group, sex, and year of attendance and were compared with non-Indigenous clients using a chi-square test and multivariate logistic regression (p < 0.05).

Results From 2006 to 2011, 7,103 (4.2%) Aboriginal people and 161,626 (95.8%) non-Indigenous people attended participating sexual health services that see large numbers of people at risk of Chlamydia positivity in Aboriginal and Torres Strait Islander females and non-Indigenous males and females between 2006 and 2011 (p-trend < 0.01). On multivariate analysis, positivity was associated with younger age, being heterosexual and living in Queensland in both Aboriginal men and women. In addition, in Aboriginal men, positivity was associated with not living in a remote area, and not having sex overseas; and in Aboriginal women, it was associated with attending in 2010 or 2011.

Conclusion The high Chlamydia positivity rates and increases over time highlight the need for enhanced prevention and screening programmes in Aboriginal people in Australia.
