The study was conducted in the districts of Marracuene, Katembe, specifically the role of orphanhood and OVC status in predicting child vulnerability. Among them are: household wealth status, education and nutrition, legal protection, education, and psychosocial outcomes among children and we measured differences in these outcomes based on whether households care for OVC and on poverty status. We disaggregated household level data in order to show the differences between (1) poor households taking care of OVC, (2) poor households not taking care of OVC, (3) non-poor households with OVC, and (4) non-poor households without OVC. This categorization allows us to demonstrate disparities among households and highlights the most vulnerable households.

OVC status was found to be an independent predictor of poor child outcomes in terms of food security, nutritional status, health, psychosocial wellbeing, and education. For example, among children under five years old, poor OVC households were more than twice as likely to have a child go hungry a day and night compared to poor non-OVC households. Among 5–11 year olds, poor OVC were more likely to be behind in grade-for-age compared to poor non-OVC and more than twice as likely compared to non-poor, non-OVC. In logistic regression models, poor OVC were 2.7 times more likely to be out of school compared to non-poor, non-OVC.

Conclusion

Our study shows that PLWHA treated with ART are more likely to experience depressive symptoms, particularly in the earlier treatment stages. This suggests a critical need for psychological support alongside initiation of treatment. Further work to identify specific patterns and causes of these symptoms and effective ways of managing them is recommended.

**Elements of the ISEAN-Hivos Monitoring and Evaluation Toolkit: Responding to the Challenge of Quality M&E Systems Implementation in a Regional HIV Program Context**

A Lesmana, Hivos, Jakarta, Indonesia

**Introduction**

In 2010, to address the increased vulnerability of MSMs as well as Transgenders to HIV transmission especially in the context of South East Asia, ISEAN and Hivos, jointly submitted a regional proposal to the Global Fund Round 10. The programme’s goal is to reduce the vulnerability and risks of MSM and TG to HIV infection in the island countries of Southeast Asia. This grant was approved and has since then been called, the ISEAN Hivos Program. Part of the challenge of implementing a regional programme is being able to fulfill its monitoring and evaluation requirements. In the initial phase of the ISEAN-Hivos implementation, efforts were undertaken to manualize the Programs M&E Requirements leading to the development of an M&E Toolkit.

**Methods**

This presentation provides a description of the ISEAN-Hivos Toolkit and shares the principles that it followed to come up with a tool that can be applied in implementing an HIV-prevention project, targeting MSMs and TGs in Indonesia, Malaysia, Philippines and Timor Leste. The ISEAN-Hivos M&E Toolkit is comprised of the following:

1. Approved M&E Plan and Performance Framework
2. M&E Reporting Templates and Tools
3. Unique Identifying Code Guidelines
4. ISEAN Hivos Calendar for Reporting

**Conclusion**

The experience of ISEAN-Hivos in fielding its M&E Toolkit provides empirical evidence of the value of manualization of programme management tools and guidelines in coordinating a cross-country regional HIV grant, which can provide learning for similar initiatives in various geographical contexts.

**OVC Status as Predictor of Poor Outcomes in Children: Combination of Household Poverty and Caring for OVC Has Worse Child Outcomes**

G Biemba, Boston University, Boston, MA, United States

According to scientific literature there are various markers of child vulnerability. Among them are: household wealth status, education levels of caregivers, living arrangements, relationship to head of household, Orphanhood, and OVC status. This paper examines specifically the role of orphanhood and OVC status in predicting child outcome in health, education, access to food and nutritional status. The study was conducted in the districts of Marracuene, Katembe, Dondo, and the administrative post of Natókire in Mozambique. We conducted a household survey of 1,759 households with 5,726 children aged 0–17 years. This Abstract focuses on children under the age five years only. We examined shelter, health, food security and nutrition, legal protection, education, and psychosocial outcomes among children and we measured differences in these outcomes based on whether households care for OVC and on poverty status. We disaggregated household level data in order to show the differences between (1) poor households taking care of OVC, (2) poor households not taking care of OVC, (3) non-poor households with OVC, and (4) non-poor households without OVC. This categorization allows us to demonstrate disparities among households and highlights the most vulnerable households.

Conclusions

Health education of youth improves their knowledge of sexual behaviour, provides support and develops skills needed for avoiding risk-taking behaviour, as well as preventing major STIs.

**The Effect of Advanced Partner Notification for People Living with HIV and AIDS**

Alesa Queralt, 1E Ademovic, 2M Seremet. School of Medicine, University of Sarajevo, Sarajevo, Bosnia and Herzegovina; 3UC U, Sarajevo, Bosnia and Herzegovina

**Introduction**

Sexually transmitted infections (STIs) have become a leading global public healthcare problem. The aim of the study was to determine and evaluate certain aspects of sexual behaviours among medical students in Sarajevo.

**Methods**

The two parts of the survey were cross-sectional analysed among 188 and 220 students by means of valid self - reported questionnaires in 2011/2012 and 2012/2013 at University of Sarajevo, BaH.

**Results**

In the first part of the survey a total of 188 students were observed, out of which in the group 18–21 of age – 35.3% males and 64.7% females and in the group of 22–25 of age – 50.9% males and 49.1% females, respectively. Sexual experience have had 67.5% of students, out of which at the age of ≤ 16–86.9% males and 13.1% females, while at the age of ≥ 17–46.1% males and 53.6% females. In the last 12 months 56.9% males used condoms each time during sexual intercourse as well as 41.5% females. In the second part of the survey a total of 220 students were observed, out of which in the group 18–21 of age-31.4% males and 68.6% females; in the group of 22–25 of age-40.5% males and 59.5% females; in the third group ≥ 26 of age-46.0% males and 54.0% females. Sexual experience have had 53.6% of students, out of which at the age of ≤ 16–94.7% males and 0.5% females, while at the age of ≥ 17–47.5% males and 52.5% females, respectively. In the last 12 months 33.8% males used condoms each time during sexual intercourse as well as 30.2% females. There was not a significant difference in condom use in relation to sexual experience, provides support and develops skills needed for avoiding risk-taking behaviour, as well as preventing major STIs.

**Conclusions**

Health education of youth improves their knowledge of sexual behaviour, provides support and develops skills needed for avoiding risk-taking behaviour, as well as preventing major STIs.
