Background/introduction Surveillance of gonococcal infection in Scotland has demonstrated variation in the prevalence of Neisseria gonorrhoeae multi-antigen sequence types. Some appear to circulate extensively, other sequence types (STs) may be recorded only once.

Aim(s)/objectives We aimed to review the epidemiology of gonococcal infection resulting from unique STs and examine for any association between unique STs and antibiotic resistance patterns.

Methods All gonococcal isolates from Lothian with a ST unique to Scotland, identified July 2006–October 2013, were included in the study. A control group of 76 patients infected with commonly circulating STs was also identified from the same study period.

Results 92 cases of N. gonorrhoeae with unique STs were identified. Of these, 55 were truly distinct and categorised as ‘unique and different’. The remaining 33 cases had STs which differed only slightly from locally circulating types and were likely to have evolved due to mutation of common strains. These were categorised as ‘unique and similar’. Patients infected with ‘unique and different’ STs were significantly more likely than controls (p < 0.5) to have had recent sexual contact outside of Europe and/or had a recent sexual partner of non-British nationality. However, they were no more likely to have a significantly altered antibiotic resistance profile, though there was a trend towards increased antibiotic resistance.

Discussion/conclusion Gonococcal strains from non-European countries may be associated with antibiotic resistance. Identification of a ‘unique and different’ sequence type raises the possibility of an imported strain of gonococcal infection and demands particular vigilance in looking for antibiotic resistance.

Background/introduction The English National Chlamydia Screening Programme focuses on prevention, control and treatment of chlamydia in sexually active under-25 year olds. A greater understanding of where young adults attend services helps to inform commissioners of where to focus resources within community settings.

Aim(s)/objectives To investigate whether young people return to the same type of primary care / community (i.e. non-Genitourinary Medicine) service for re-testing.

Methods Surveillance data from the Chlamydia Testing Activity Dataset (CTAD) was used to identify patient attendances at primary care / non-GUM community services among 15 to 24 year olds and monitor re-testing within and between community services.

Results From January 2012 to December 2013, 1,333,718 young people underwent 1,626,106 chlamydia tests. The majority of people (84%) were tested only once. Of those who tested more than once, 57% used the same venue type. General Practice (GP) was the most commonly re-attended service for patients who tested twice (55.3%). Among those who tested three or four times, there was an increasing preference for community sexual health services (50% and 57% respectively).

Discussion Patients re-attended GP services more often than other venue types but for subsequent attendances more specialised community sexual health services were used. Very few repeat visits were made to pharmacies or pregnancy termination services. These data show that patients are likely to return to services they know when they require a further test. This should be taken into consideration by commissioners implementing new retesting guidance from the NCSP.
