**Discussion/conclusion** The plantar rash of 2°Syph is probably seen mostly in thinner areas of arch-of-foot epithelium because vasculitis is hidden under the thickly keratinised weightbearing sole. Any rash covering both areas must raise the possibility of an alternative or double diagnosis or an especially florid presentation.

**P32 SURVEY OF KNOWLEDGE ABOUT GONORRHOEA IN PATIENTS WITH GONORRHOEA**

1,2Lauren Amor*, 2Joanna Peters, 2Angela Dunne, 2John Paul, 2Gillian Dean, 2Fiona Creswell. 1Brighton and Sussex Medical School, Brighton, East Sussex, UK; 2Brighton and Sussex University Hospitals, Brighton, East Sussex, UK

10.1136/sextrans-2015-052126.76

**Background/introduction** Gonorrhoea is a public health problem due to rising incidence and antimicrobial resistance. Health education is a proven health intervention. Planning interventions requires understanding of views of target groups.

**Aim(s)/objectives** Describe subjective knowledge of gonorrhoea and preferred methods of health education in individuals presenting with gonorrhoea. Identify differences across specified age groups and sexual orientation.

**Methods** A prospective study recruited 121 individuals with gonorrhoea. Participants completed a questionnaire. Data from questionnaires were anonymised and analysed.

**Results** Demographic aspects of this study are presented in a separate abstract. Subjective knowledge about gonorrhoea increases with age and is similar in MSM and heterosexuals. Popularity of mobile Apps decreases with age; 43.8% of 18 yr olds, increases with age and is similar in MSM and heterosexuals. Data was retrospectively collected on all patients diagnosed with rectal CT from 1st October 2010 to 1st October 2013 at a large, inner city sexual health clinic. Information was collected on gender, concurrent sexually transmitted infection (STI), treatment received, adherence to antibiotic, risk of re-infection and 4-week test of cure (TOC). Assessment of risk of re-infection included completion of telephone follow-up, verification of contact tracing of regular partners and absence of unprotected sexual intercourse.

**Results** 959 patients were diagnosed with rectal CT during the study period. 660 (68.8%) patients received doxycycline therapy in line with local treatment protocol. TOC was performed in 473 (71.7%) patients, of which 22 (4.7%) were positive. Risk of re-infection was excluded in 5 cases (22.7%) and considered possible treatment failures.

**Discussion/conclusion** The treatment failure rate of doxycycline for rectal CT identified in this study is similar to that reported with azithromycin and is contradictory to our previous findings. The longer study period with larger study population may explain this result. These findings suggest that TOC following treatment of rectal CT is necessary and would not support preferential use of doxycycline over azithromycin.

**Category:** Clinical case reports

**P34 TWO CASES OF ACUTE HEPATITIS E CAUSING A TRANSIENT TRANSAMINISIT IN HIV INFECTED MSM**

David Lawrence*, Yvonne Gilleece, Amanda Clarke, Martin Fisher, Daniel Richardson. Lawson Unit, Brighton and Sussex University Hospitals NHS Trust, Brighton, UK

10.1136/sextrans-2015-052126.78

**Background/introduction** Hepatitis E Virus (HEV) is increasing in incidence. Transmission routes include faecal-oral, blood and zoonotically. Patients present with no symptoms; elevated liver enzymes; acute/chronic hepatitis and/or neuropathy. Evidence suggests poorer outcomes among HIV+ patients.

**Aim(s)/objectives** To describe known cases of HEV/HIV co-infection within a cohort of 2200 HIV+ patients.

**Methods** We present two cases.

**Results** Patient-1, a 63-year-old asymptomatic HIV+ MSM with a 22-year history of HIV, recently re-started Truvada/darunavir/ritonavir: CD4 393(17%) cells/mm³ and HIV VL 327,824 copies/ml. Routine bloods identified newly elevated ALT 477 IU/L: other liver function, clotting and liver ultrasound were normal. He had no STIs diagnosed in the preceding year nor risk factors for HEV. A hepatitis screen was performed. HEV IgG, IgM and PCR were positive. Treatment was supportive, with normalisation of ALT and negative HEV-PCR after eight weeks. Patient-2, a 41-year-old asymptomatic MSM with an 11-year history of HIV was ART naïve: CD4 682(25%) cells/mm³ and HIV VL 13,109 copies/ml. Routine bloods identified newly elevated ALT 459 IU/L: other liver function, clotting and liver ultrasound were normal. He had no STIs diagnosed in the preceding year.
Correction

The figure given in the conclusion for the treatment failure rate of doxycycline for rectal CT at 19.2% is incorrect and refers instead to the proportion of positive test of cures that were attributed to treatment failure. It should read: “The treatment failure rate of doxycycline for rectal CT identified in this study was 0.9% compared with 0% that we had previously reported.” This alters the authors’ recommendations to: “Our data does support the recommendation of preferential use of doxycycline over azithromycin for the treatment of rectal CT” and “these findings suggest that test of cure (TOC) does not need to be performed in patients treated for rectal CT with doxycycline”.
