Introduction Neisseria gonorrhoeae resistance to extended-spectrum cephalosporins as well as treatment failures with ESCs has been increasingly reported in many countries globally. These increasing trends together with the limitation of drugs of choice lead gonorrhoea to become a global health concern. Hence, we aimed to reveal more understanding on the physiological response of gonococci to ESCs using proteomic approach.

Methods N. gonorrhoeae reference strain was grown with or without a subinhibitory dose of ESCs. Protein expression was determined by 2-dimensional gel electrophoresis in conjunction with MALDI-TOF/TOF MS analysis.

Results In total, 14 and 13 proteins were significantly altered expression following exposure to ceftriaxone and cefixime, respectively. Most of expressed proteins shared a similar expression pattern in response to ceftriaxone and cefixime reflecting similarities in antibiotic mechanisms. ESC antibiotics triggered proteins in a variety of functions, such as membrane protein, transport system, energy metabolism, and stress response, which would help gonococci to survive under drug stress. Interestingly, the subinhibitory dose of ESCs also triggered the expression of gonococcal virulence factors (e.g. azurin and peptidyl-prolyl isomerase), which might be an adaptation mechanism of gonococci in ESC stress and also affect the outcome of gonococcal infection.

Conclusion The present work might provide new insights into physiological adaptive networks of gonococci to antimicrobial agents and more understanding toward the mechanism of action, which subsequently may benefit for the further drug discovery of new antimicrobials to combat with resistant gonococci.
We described the reported samples by sex and age and characterised isolates tested in NRL by resistance patterns. We calculated proportions and medians, together with interquartile range (IQR), where appropriate.

**Results** Between April and December 2014 we received information on 651 isolates tested in 19 laboratories. Altogether, 90.3% isolates were from men and 8.5% from women. Median age of tested men was 36 (IQR 29–49) and women 28 (IQR 22–41) years.

NRL received 502 isolates, 342 were vital and 253 were tested for AMR. From those 0 were resistant towards ceftriaxone, 1.6% towards cefixime, 11.1% towards azithromycin, 73.1% towards ciprofloxacin, and 30.4% towards penicillin. Further 37.9% and 50.6% isolates were intermediate susceptible to Azithromycin and to Penicillin. From 205 isolates tested for beta-lactamase, 23.9% were positive.

**Conclusion** In Germany isolates tested for NG-AMR were mostly from men. We assume that a substantial proportion of these isolates could be from men having sex with men. NG-AMR to ceftriaxone and cefixime remains low, while resistance and intermediate susceptibility to azithromycin, ciprofloxacin and penicillin is substantial. Monitoring of NG-AMR should be highly prioritised.

**Introduction** Neisseria gonorrhoeae is one of the most important pathogens causing sexually transmitted infection. Resistant N. gonorrhoeae strains against several antimicrobials are increasing worldwide. In this study, the trends of antimicrobial susceptibility among N. gonorrhoeae strains isolated from male patients with urethritis were investigated as the second Japanese national surveillance, which was conducted by a Japanese surveillance committee.

**Methods** The targets were male patients older than 16 years with urethral discharge and symptoms of urethritis. Urethral discharge was collected from patients at 26 medical facilities from March 2012 to January 2013 and the antimicrobial susceptibility of strains were tested.

**Results** From 151 patients (median age 32 years), 103 N. gonorrhoeae strains were tested for susceptibility to 20 antimicrobial agents. None was susceptible to penicillin G (MIC: ≥0.06 μg/mL). The prevalence of penicillinase producing N. gonorrhoeae or chromosomally mediated resistant N. gonorrhoeae was 1.9% or 20.8%, respectively. The susceptible rate for fluoroquinolones such as ciprofloxacin or levofloxacin was 20.3%. The susceptible rate for cefixime was 89.3%, that decreased from 98.8% at 2009. No ceftriaxone-resistant strains founded. The prevalence of less susceptible strain to ceftriaxone (MIC: 0.125 μg/mL) was 10.7%. No azithromycin high-resistant strain found and 5 strains (4.9%) had MIC ≥0.5 μg/mL. Among all strains, 83 strains (80.6%) were resistant to more than 2 kinds of antimicrobials and 42 strains (40.1%) was included to the criteria as multi-drug resistant N. gonorrhoeae.

**Conclusion** The antimicrobial susceptibility of N. gonorrhoeae was not different between 2009 and 2012–2013, in Japan.

**Disclosure of interest statement** Nothing to declare.

**PO5.12** **ANALYSIS OF BACTERIAL FLORA OF THE URINE SPECIMENS FROM MALE PATIENTS WITH URETHRITIS BY THE CLONE LIBRARY METHOD BASED ON THE 16S rRNA GENE**

**Introduction** Chlamydia trachomatis, Mycoplasma genitalium or Trichomonas vaginalis are the pathogens for non-gonococcal urethritis, but pathogenicity of other microorganisms for the male urethral has not be confirmed. In this study, the bacterial flora of urine specimens from male patients with urethritis was analysed by the clone library method based on the 16S rRNA gene.

**Methods** The first voided urine specimens of male patients with urethritis were collected. The detection of Neisseria gonorrhoeae, C.trachomatis were examined by transcriptional mediated amplification (TMA) method and M. genitalium, Ureaplasma urealyticum, Ureaplasma parvum and Mycoplasma hominis were examined by real-time PCR method. The urine specimens were strained by Ethidium bromide and the number of bacterial cells were counted. DNA was extracted from the urine and amplification of the 16S rRNA gene via PCR (universal primers) and determination of the nucleotide sequences of 96 colonies were performed. The homology search was performed with a basic local alignment search tool (BLAST) using in-house software system and phylogenies of bacteria in each specimens were analysed.

**Results** Urine specimens were collected from 38 patients and the divided to 4 group; gonogococcal urethritis (n:9), chlamydial urethritis (n:12), non-chlamydial non gonococcal urethritis detecting with Ureaplasmas or Mycoplasmas (UM+NCNGU, n:15) and non-chlamydial non gonococcal urethritis detecting without Ureaplasmas or Mycoplasmas (UM-NCNGU, n:22). Cell numbers were higher in UM+NCNGU than in UM-NCNGU. Among specimens, 2427 clones in 38 bacterial flora could be analysed and 91 bacterial phylogenies were detected together with N.gonorrhoeae, C.trachomatis, Mycoplasmas or Ureaplasmas positive specimens among chlamydial urethritis or UM+NCNGU groups. Gardnerella vaginalis was detected with Mycoplasma/Ureaplasma in Chlamydial urethritis or UM+NCNGU.

**Conclusion** The clone library method by using 16S rRNA gene is the new technology for analysis the bacterial flora of urine with urethritis. The relationship between G. vaginalis and Ureaplasma/Mycoplasma was found by this analysis.
