Introduction Recurrent vulvovaginal candidiasis (RVVC) results in significant physical, financial and psychological sequelae for women, and many women report that VVC affects their intimate relationships. The aetiology of RVVC remains uncertain, and some studies suggest sexual intercourse may be responsible for transmission of Candida species. No publications have documented the affect of sexual intercourse on vaginal candida colonisation.

Methods Fifty nine participants who were culture positive for Candida spp. at screening took part in a randomised controlled trial investigating the effect of oral garlic and placebo on vaginal candidal colonisation. Participants self-collected daily vaginal swabs during the two weeks before menstruation. They kept a daily diary and recorded incidence of sexual intercourse and abnormal vaginal symptoms. Swabs were analysed for quantitative colony counts of candida before and after sexual intercourse.

Results There were 149 episodes of sexual intercourse in participants reporting sexual activity (n = 38) over the two week study period. Colonisation levels rose the day following sexual intercourse in 51 episodes, and fell in 56 episodes. In 42 episodes of sexual intercourse, the levels remained the same or women were culture negative on the day following and two days following sexual intercourse. On fifty occasions women had symptoms (itch, abnormal vaginal discharge) on the day of sexual intercourse, and 41 women reported abnormal symptoms two days after sexual intercourse. In 75 episodes, there were no abnormal symptoms the day of, or the day following sexual intercourse.

Conclusion In this study, sexual intercourse, colonisation levels and abnormal vaginal symptoms appeared to be unrelated. Further investigation is recommended to disprove and abnormal vaginal symptoms following sexual intercourse experienced by women with RVVC.

Disclosure of interest statement No pharmaceutical grants were received in the development of this study.

Results Overall, healthy young women had differing vaginal community states. Onset of non-coital and coital sexual activities does not exert a significant effect on the composition of vaginal bacterial communities. The vaginal community-state with the greatest stability over time consisted of states predominated by L. crispatus and L. iners with median Bray-curtis dissimilarity values of 12.4 and 17.6 respectively (p = 0.005 and 0.024). Vaginal microbiomes dominated by other Lactobacillus spp. and non-Lactobacillus spp. gave rise to the most variability over time (dissimilarity values of 41.1 and 66.8). Non-coital and coital sexual activity within this subset of participants did not have any significant effect upon the stability of vaginal bacterial communities (p = 0.3714).

Conclusion L. crispatus and L. iners are most commonly found to dominate sexually inexperience women and convey the most stable environment over time. The initiation of new sexual activities does not appear to have any persistent effect on the vaginal microbiome of young women.

P07.02 EVALUATION OF THE HOLOGIC TRANSCRIPTION MEDITATED AMPLIFICATION ASSAY FOR DETECTION OF MYCOPLASMA GENITALIUM FROM URINE SAMPLES

1,2,3SN Tabrizi, 4AM Costa, 5S Lowe, 5CS Bradshaw, 6CK Fairley, 1,2,3SM Garland. 1Munro Children’s Research Institute; 2The Royal Children’s and the Royal Women’s Hospitals; 3University of Melbourne; 4Hologic; 5Melbourne Sexual Health Centre

Introduction M. genitalium is an emerging sexually transmitted pathogen, with a strong association with urethritis, cervicitis and pelvic inflammatory disease. Detection of this bacterium by routine culture is not practical and routine diagnosis and screening for M. genitalium by molecular techniques has been hampered by lack of readily available commercial assays. A preliminary version of a commercial amplification assay is currently available on the Panther platform and was evaluated against an in-house qPCR assay currently in use for routine diagnostics.

Methods Overall 1000 consecutive urine samples from men and women were utilised for this evaluation. Over the course of 3 months, urine samples were obtained from consecutive symptomatic men and women being screened for M. genitalium at Melbourne Sexual Health Centre, as well as women being screened prior to termination of pregnancy at the Royal Women’s Hospital, Melbourne. The primary Hologic assay targeting 800bp region of 16s rRNA was compared to the in-house diagnostic assay which targets a 517bp region of 16s gene, as well as a second 16s rRNA target available on the Hologic platform.

Results The comparison of the two targets available on the Hologic platform showed very high correlation (k = 0.97 95% CI 0.93–1.00). Comparison of primary Hologic assay to in-house 16S qPCR assay also showed very good correlation (K = 0.84 95% CI 0.75–0.93). Overall, both primary and secondary Hologic assays on Panther were more sensitive than the 16S qPCR for detection of M. genitalium in urine specimens.

Conclusion The M. genitalium assay on the Hologic platform integrated well with the laboratory procedures allowing rapid testing and possibility of rapid and accurate reporting using integration with laboratory information system. Overall the Hologic assay for detection of M. genitalium offers a simple, accurate and sensitive platform for diagnostic laboratories for detection of this important upcoming pathogen.

Disclosure of interest statement Hologic supplied the diagnostic kits and the Panther platform to conduct this study.

P07.03 CLINICAL PERFORMANCE EVALUATION OF A NEW, RAPID POINT-OF-CARE SYSTEM FOR DETECTING CHLAMYDIA TRACHOMATIS

1DM Pearce*, 2S Alexander, 3B Avlett, 4SA Bannister, 5TRK Edwards; 6MT Green, 2JDC Ross, 5CA Ison; 7Atlas Genetics; 8Public Health UK; 9University Hospitals Birmingham, UK

Introduction The Atlas Genetics io™ system is a new rapid molecular diagnostic platform designed to test for infectious diseases at Point of Care (POC). The test process is fully automated and utilises a novel nucleic acid detection technology. There is no specimen processing and it provides a result in 30 min. This preliminary evaluation compared the performance of the Atlas Genetics io™ Chlamydia trachomatis (CT) test to routine diagnostic testing using the APTIMA Combo 2 test (AC2, Hologic Gen-Probe) for the detection of CT.

Methods Two self-collected vulvo-vaginal swabs were obtained from women presenting at a genitourinary medicine clinic; swabs from alternate patients were placed in collection buffer and tested using the AC2 test or the io™ CT assay as the first test. Any sample giving a discrepant result was retested using the residual buffer from the io™ CT assay using the artus® C. trachomatis Plus RG PCR kit (Quagen). A true positive result was defined as positive with at least two of the three tests.

Results Of the samples collected from 193 women, 18 were determined to be true positive results for C. trachomatis, of which one sample was positive with the AC2 and artus CT test but negative with the io™ CT test. Three io™ false positive results were reported out of 175 samples that were negative when tested using the AC2 and artus tests. Based on a provisional cut-off, this resulted in a sensitivity and specificity of 94.4% and 98.3%, respectively for the io™ CT test.

Conclusion The Atlas Genetics io™ CT test was shown to deliver laboratory-equivalent results within 30 min, on a system designed to be used in the STI clinic or similar POC setting, that is easy-to-use and gives results that require no interpretation or analysis.

Disclosure of interest statement BA, SAB, TRKE, MTG and DMP receive salaries and stock options from Atlas Genetics Ltd. This study was funded by the Technology Strategy Board, project No. 100845.

P07.04 NEW MOLECULAR POINT-OF-CARE TEST IMPROVES TIMELINESS OF TREATMENT FOR CHLAMYDIA TRACHOMATIS (CT) AND NEISSERIA GONORROEA (NG) IN A REMOTE ABORIGINAL HEALTH CLINIC

1R Huang*, 2J Ward, 3A Tangey, 3A Causer, 4R Guy, on behalf of the TTANGO investigators. 5Ngaanyatjarra Health Service; 6South Australian Health and Medical Research Institute; 7Ngaanyatjarra Health Service; 8Kidby Institute

Introduction High CT and NG prevalences have been observed in remote Aboriginal communities for decades. Testing and treatment are key prevention strategies, yet considerable delays in treatment occur, due to distances from laboratories and difficulties recalling patients. The TTANGO (Test, Treat AnD Go) randomised controlled trial is the first to evaluate whether a new point-of-care CT/NG test (GeneXpert) can improve the timelines of treatment and reduce re-infections rates in remote Aboriginal communities.

Methods In the context of TTANGO, we conducted an interim analysis to compare timelines of treatment before and after the point-of-care test was introduced at one of the 12 TTANGO sites. This site is one of seven remote clinics managed by Ngaanyatjarra Health Council (NHC), an Aboriginal health service in South Australia.

Results Overall, 777 people were tested for CT/NG, 81 (10.4%) were positive; highest in 15–19 year olds (15.4%). In the point-of-care period, 40/40 (100%, 95% CI: 91.1–100) of people with a positive CT/NG point-of-care test received treatment, and of these 90% were treated in 24 h, with a median time-to-
