The platform was validated by testing Chlamydia trachomatis infection from patient-collected vaginal swab samples. Volunteers enrolled in an internet-based Chlamydia screening program, where two sets of swabs were self-collected and mailed back to our lab. One set of swabs was analysed using the gold standard Gen-Probe AC2 CT assay. The second set of swabs was tested using the mobiLab platform. The two results were in agreement for 20 out of 20 samples at a time threshold of 30 min, demonstrating that the droplet assay performance is comparable to the gold standard for the samples tested. To our knowledge, this abstract presents the first smartphone-based NAAT platform that integrates sample preparation, amplification and data processing.

003.1 CORRELATES OF REPEAT ANORECTAL INFECTIONS AMONG MEN WHO HAVE SEX WITH MEN

YIS Kong*, S Tabrizi, CK Fairley, S Phillips, W Huston, LA Vodstrcil, M Chen, CS Bradshaw, JS Hocking, JC Fairley, J Telfer, J Pujak, IJ Peel, SM Garnett, MYC Chen, JH Chen

Introduction There is increasing concern about azithromycin treatment failure for rectal chlamydia. Higher organism loads have been reported at the rectal site compared to other sites (genital/oral) and higher organism load may be associated with treatment failure in women, but little data are available among men who have sex with men (MSM). This study examined the association between organism load and repeat rectal chlamydia infection in order to investigate possible mechanisms for treatment failure.

Methods Stored rectal chlamydia positive samples from men attending Melbourne Sexual Health Centre between July 2008 to October 2013 were analysed for organism load and chlamydia serovar. Men were included if they had a follow-up test within 100 days of the index infection.

Results There were 292 chlamydia positive index rectal swabs available for analysis. Organism load and serovar were assessable for 284 swabs — 44 cases had one repeat positive result, 5 cases had two repeat positives and 181 MSM had a negative result within 100 days of their index positive result. Among the 230 index infections, 33% were serovar G, 30% were D, 15% were J, 9% were E, 7% were L2, 3% were B and 2% were F. The cumulative incidence of repeat rectal chlamydia within 100 days was 21%. Among those men who had a repeat positive result, all but three (3%) were the same serovar. Organism load was higher in index cases of men who had a repeat infection compared with those who did not (p < 0.01).

Conclusion Repeat rectal chlamydia is common within 100 days among MSM attending MSHC. Most repeat infections were of the same serovar suggesting these infections were either treatment failure or re-infection from an infected partner. High organism load was associated with repeat infection suggesting a possible role in treatment failure.

003.2 THE CONTRIBUTION OF MYCOPLASMA GENITALIUM TO THE AETIOLOGY OF SEXUALLY ACQUIRED PROCTITIS IN MEN WHO HAVE SEX WITH MEN

M Blissesso*, SN Tabrizi, CS Bradshaw, CK Fairley, J Telfer, M Pujak, JI Peel, SM Garnett, MYC Chen, JH Chen

Introduction To determine the contribution of Mycoplasma genitalium to the aetiology of sexually acquired proctitis in HIV positive and HIV negative men who have sex with men (MSM).

Methods Consecutive MSM diagnosed clinically with proctitis between May 2012 and August 2013 were tested for: rectal M. genitalium by real time PCR assay; chlamydia by strand displacement assay; gonorrhoea by culture; and herpes simplex virus (HSV) by in-house PCR. M. genitalium load was determined by qPCR assay targeting the MgpA gene. The loads of rectal M. genitalium in men with symptomatic proctitis were compared to those in a control group of men (ratio 1:1) with rectal genitalium but no symptoms of proctitis.

Results Among 154 MSM with proctitis, rectal M. genitalium was detected in 12% (18/154, 95% CI: 6.9–17.1%). Rectal M. genitalium was significantly more common among HIV positive men (10/48, 21%; 95% CI: 9.5–32.6) compared with HIV negative men (8/106, 8%; 95% CI: 2.9–13.1, p = 0.02). Among HIV positive men the rate of M. genitalium was comparable to that for chlamydia (21%), gonorrhoea (25%) and HSV (19%).

The median load of M. genitalium among 18 men with symptomatic proctitis was significantly higher than the median load among 18 controls who had asymptomatic rectal M. genitalium (4.82 log10 load/sample versus 3.81 log10 load/sample, p = 0.016).

Conclusion M. genitalium was common among MSM with symptomatic proctitis, especially those with HIV. Comprehensive testing for multiple sexually acquired pathogens in MSM presenting with proctitis is required and should include testing for M. genitalium.

003.3 THE PREVALENCE OF MYCOPLASMA GENITALIUM AND CHLAMYDIA TRACHOMATIS AT VARIOUS ANATOMICAL SITES OF MEN WHO HAVE SEX WITH MEN IN FIVE CITIES OF CHINA

J Jiang*, P Liu, NX Cao, XD Gong

Introduction To determine the prevalence of Mycoplasma genitalium and Chlamydia trachomatis in urethra, rectum and pharynx of men who have sex with men (MSM) in China, and to analyse the association between the agents detection and clinical manifestations.

Methods 388 MSM were recruited at gay bars in five cities of China from September 2007 to November 2008. Rectal and pharyngeal swabs and first void urine were tested for M. genitalium and C trachomatis by PCR. Bivariate and multivariable
