HTLV-1/-2 SEROLOGY IN THE TESTS BATTERY FOR MOTHER-TO-CHILD TRANSMISSION OF HIV IN

Methods
A retrospective cohort carried out at the major HIV reference centre in Bahia, Brazil. Medical records of PWLH attended at prenatal care were reviewed from January 2011 to December 2013. HIV VL and TCD4+ count data were obtained from the national database. Statistical analyses were performed with SPSS 20.0.

Results
A total of 235 PWLH enrolled in the study, of which 29.4% were LP. Among the latter, the mean age was 28.3 (±6.9) years, similar to the EA group. Thirty percent of the LP had <8 schooling years (p=0.16), 40.7% were single (p=0.64), 24.6% reported alcohol use (p=0.15), 1.6% drug use (p=0.44) and only 16.7% regular condom use (p=0.92). The majority of LP (62.9%) had partners with unknown serological status, 25.7% had seroconcordant and 11.4% had serodiscordant partners (p<0.01). LP predominantly had HIV diagnosis during pregnancy (60.9%; p<0.01) and were ARV naïve (78.1%; p<0.01), while only 14.5% were on ART at conception (p=0.01). As for the initial ART regimen during pregnancy, 89.9% of LP were using a protease inhibitor based regimen and 11.6% had had regimen changes during pregnancy (p=0.36). LP had a higher initial VL (log_{10} 3.4; p<0.01) and those with recent diagnosis also had higher VL (log_{10} 3.8; p=0.02). LP were more likely to not have a second VL during pregnancy or early peripartum (33.3%; p=0.01). VS was less achieved (34.8% vs 71.8%; p<0.01; OR 4.7, CI95% 2.3–9.6) by the LP group.

Conclusion
LP showed an increased risk of MTCT, with recent HIV diagnosis, higher VL at prenatal onset and a lower rate of VS. Thus, the use of integrase inhibitors would be a better choice for this population, since it promotes a quickly decrease of VL.

P3.76 HTLV-1/-2 SEROLOGY IN THE TESTS BATTERY FOR FOLLOWING UP PATIENTS WITH VIRAL HEPATITIS IN BRAZIL

Introduction
Brazil is endemic for HIV-1, HTLV-1 and HTLV-2, these retrovirus share routes of transmission with HCV and HBV, thus coinfections can occur. Several studies tried to evaluate the impact of human retroviruses on the course of HCV infection, and association of HTLV-1 with spontaneous clearance of HCV, mostly in HIV coinfected patients, and less hepatic injury were detected. In contrast, an increase in HCV viral load in HIV and/or HTLV-2 coinfected individuals was described. Concerning HBV infection, one study showed higher rate of HBV antigenemia in HIV/HTLV-1 coinfected patients. Thus, searches for HTLV infections in HCV and HBV infected patients have prognostic value.

Methods
Plasma samples from 1244 individuals sent to Instituto Adolfo Lutz for measuring HCV and HBV viral load: 622 HCV+ (G1=343 male, 279 female), and 622 HBV+ (G2=327 male, 295 female) were evaluated for HTLV-1/-2 infection by enzyme immunoassay (EIA, HTLV-I/II, Gold ELISA, REM), and confirmed by line immunoassay (INNO-LIA HTLV-I/II, Fujirebio). HIv infection was detected by immunochromatographic assay (Rapid Check HIV 1+2, UFFS).

Results
On screening test 44 plasma samples reacted, and HTLV-1 was confirmed in 25 samples [20(G1), 5(G2)]. HTLV-2 was detected in 16 samples [13(G1), 3(G2)]. Two samples were indeterminate, and one negative (G2). The overall prevalence of HTLV in HCV+ was 5.3% (3.2% HTLV-1% and 2.1% HTLV-2), and HBV +1.3% (0.8% HTLV-1% and 0.5% HTLV-2). No difference in the median age of patients was detected between HCV-infected and HCV/HTLV coinfected (50.7 vs. 50.6 years), also in HBV and HVTLL/HBV coinfected (45.8 vs. 53.5 years). In HCV/HTLV coinfected patients 30.3% were HIV+, while in HBV/HTLV coinfected patients, all except one were HIV+.

Conclusion
The results emphasise the need for searching HTLV infections mostly in patients with HCV. Thus, we suggest to include the serology for HTLV in the tests battery for following up the hepatitis virus infected patients in Brazil, regardless of their HIV status.

P3.77 MOTHER-TO-CHILD TRANSMISSION OF HIV IN SOUTHERN SANTA CATARINA, BETWEEN 2005 AND 2015: ASSESSMENT OF SEROCONVERSION

Introduction
In Brazil, 92,210 HIV-infected pregnant women were notified from 2000 through June 2015, most of whom living in the Southeast (40.5%) and South (30.8%). Detection rates of pregnant women living with HIV in Brazil have increased in the last ten years. In 2005, rates of seropositivity for newborns were as high as 2.0 cases per 1000 live births, which increased to 2.6 in 2014, indicating a 30.0% rise. The aim of this study was to analyse the frequency of seroconversion among newborns to HIV-positive mothers living in southern Santa Catarina, Brazil, from 2005 through 2015.

Methods
A cross-sectional study was conducted to collect secondary data. All the newborns that were exposed to HIV by vertical transmission, and attended the municipal healthcare centre between 2005–2015 participated in the study. The study included all infants between 0 and 18 months of age, exposed to HIV vertically, who attended the healthcare centre that serves 18 municipalities in southern Santa Catarina, Brazil, over the 2005–2015 period.

Results
During the study period, there were 93 exposures to HIV, of which 3 (3.2%) seroconversions were confirmed and 2 (2.1%) died of AIDS during the follow-up period. Seroconversion was associated with breastfeeding (PR=29.3; 95% CI=9.6–89.2; p=0.002) and the lack of antiretroviral therapy during pregnancy (PR=21.0; 95% CI=2.4–184.5; p=0.006).

Conclusion
The results from this study allowed us to conclude that seroconversion among newborns was 5.4%, resulting in a rate of 3.4 cases per 1000 live births, which was higher than the national average. Seroconversion was associated with

Sex Transm Infect 2017;93(Suppl 2):A1–A272
Introduction

HIV-associated lipodystrophy syndrome is a major adverse effect of highly active antiretroviral therapy (HAART), although it also occurs among people living with HIV who do not receive any pharmacological treatment. Lipodystrophy diminishes patients’ quality of life and may hinder treatment compliance or lead to its abandonment.

Methods

Cross-sectional study conducted from October 2015 to March 2016. A sample was recruited from individuals living with HIV who attended an outpatient clinic in Tubarão, state of Santa Catarina, Brazil. We collected information on demographics, lifestyle, HIV infection, and clinical aspects. Lipodystrophy was diagnosed through patient self-report associated with anthropometry.

Results

We surveyed 405 patients (most were white men; mean age 43.7 years). The mean duration of HIV infection was 74.6 months, and 90.1% of the respondents were taking antiretroviral therapy. The prevalence of lipodystrophy was 34.2%, of whom 43% had lipoatrophy, 52% had lipohypertrophy, and 5% had a mixed form. There was a statistical association between the presence of lipodystrophy and female gender (OR = 1.77 (95% CI 1.35 to 2.32)) and the duration of HIV infection (OR = 1.00 (95% CI 1.00 to 1.04)).

Conclusion

Lipodystrophy was prevalent in more than one-third of the surveyed subjects, which is a warning signal. Lipodystrophy affects quality of life and adherence to treatment, and may cause cardiovascular damage in this population.

ANALYSIS OF THE CLINICAL PROFILE AND RESULTS OF TUBERCULOSIS CASES TREATMENT IN PEOPLE LIVING WITH HIV/AIDS

Gabriela Tavares Magnabosco, Rubia Laine de Paula Andrade, Tiemi Arakawa, Maria Eugenia Fimino Brunello, Laura Terencian Campoy, Livia Maria Lopes, Aline Aparecida Monroe, Teresa Cristina Scatena Villa. School of Nursing of Ribeirão Preto/University of Sao Paulo, Ribeirão Preto – SP, Brazil

Introduction

Tuberculosis (TB) even though it is a viable cure is still recognised as a current and persistent public health problem aggravated by the rise in HIV/AIDS. The association between HIV infection and TB increases the probability of death of individuals and influences the control of both, challenging the practice of care and health policies.

Methods

This was a descriptive, quantitative-type survey, aimed to analyse the clinical profile and results of TB treatment cases in people living with HIV/AIDS in Ribeirão Preto/ Brazil in the years 2010 to 2014. Patients in the penitentiary system, under the age of 18 and who had changes in diagnosis or transfer were excluded. TB/WEB information system was used for data collection. Descriptive statistical techniques were used for data analysis.

Results

There were 224 cases of TB/HIV of which 71% were men and 29% were women; 94.2% were diagnosed with AIDS and 5.8% were HIV-infected. The clinical form of pulmonary TB was prevalent (64.7%), followed by extrapulmonary (23.2%) and pulmonary + extrapulmonary (12.1%). Regarding the clinical profile of TB, 73.7% were new cases, 14.7% relapsed and 11.6% were re-treatment due to abandonment. Regarding the associated comorbidities, there were two cases with diabetes mellitus, 15.6% alcoholism, 15.6% drug addiction and 3.1% smoking. 74.6% of the cases had to be hospitalised at some point. Regarding the result, the cure rate was 57.2%, 16.5% of the abandonment and 26.3% of death. The clinical characteristics of the subjects follow the parameter of the general population (the highest prevalence among men, followed by women).
