Introduction Men who have sex with men (MSM) are considered an important key population in South Africa. Insight in the dynamics of sexually transmitted infections (STI) is of paramount importance to address the burden of infection. We aim to characterise incident STI among South African MSM.

Methods This prospective cohort study was conducted at two primary healthcare clinics that specifically target MSM in Johannesburg City Centre and Soweto, South Africa. We recruited MSM presenting with urethral discharge and provided standard syndromic management. Participants were requested to return for follow-up testing after six weeks, or earlier in case of symptoms. A urine specimen and rectal swab were collected for molecular microbiological investigations at both visits.

Results We recruited 78 MSM of whom 69% identified as gay; 43% was HIV-infected. Neisseria gonorrhoeae was the main cause of discharge in 46 men (59%), followed by Chlamydia trachomatis in 9 (12%), Mycoplasma genitalium in 1 (1.3%) and Trichomonas vaginalis in 3 (3.8%). Rectal swabs were positive for N. gonorrhoeae (28%), C. trachomatis (13%) and T. vaginalis (3.8%). Sixty-one (78%) men came for follow-up visit. Twenty-three men (38%) had a total of 34 STI diagnosed at follow-up, including 20 urethral and 14 rectal infections. The majority of these infections (68%) were considered newly acquired STI based on microorganism detected and anatomic site involved. This includes all infections with C. trachomatis (n=5), M. genitalium (n=3) and T. vaginalis (n=9). Seventeen MSM tested positive for N. gonorrhoeae at follow-up; six of which were new infections.

Conclusion We demonstrate a high rate of repeat STI in this unique cohort of South African MSM and show that most of these infections are newly acquired. This supports the effectiveness of syndromic management for most STI, but also highlights that strengthening of prevention efforts is highly warranted. The observation of repeat N. gonorrhoeae infections is concerning and molecular typing for further analysis of these strains is underway.

HIV IN INDIGENOUS MSM IN GUATEMALA: A HIDDEN PROBLEM
Ricardo Mendizabal-Burastero, Ricardo Mendizabal-Burastero, Marco Polo Yancor. Colectivo Amigos Contra El Sida, Guatemala – Guatemala

Introduction In Guatemala, data regarding HIV epidemics doesn’t show much data about indigenous population, although nearly 50% of the population in Guatemala are indigenous. In metropolitan area, MSM HIV prevalence is around 9%. But there is not data about HIV prevalence in indigenous MSM. This data is the first report in this important group.

Methods Cross-sectional data analysis from October 2015 to July 2016. MSM were recruited as part of the implementation of Global Fund projects. Activities were implemented in three department of the Guatemalan highlands: Sololá, Totonicapan and Chimaltenango. Recruitment was performed by peers, by face-to-face or using social networks. Rapid HIV testing was performed in-site and confirmation in reference laboratory, STI were evaluated by syndromic management. Data was analysed using Stata 13.

Results 1196 MSM were tested for HIV and 293 had STI evaluation. 42% lived in Chimaltenango and 19% in Sololá. Median age was 22 years old (IQR 19–26); 40.3% of them self-reported as indigenous, 11% of them K’iche’ and 10% kakchiquel. 60% of them had high school or higher education, 58 HIV cases were diagnosed, for a global HIV prevalence of 4.8%. In indigenous MSM HIV prevalence was higher (5.1 vs 4.9, no difference). In K’iche’ MSM (N:156) HIV prevalence was higher (4.2%) than in kakchiquel (3.9%), but no difference. 18% had an STI, the most prevalent were anal warts (13%).

Conclusion HIV prevalence in indigenous MSM is lower than reported in Guatemala city, however is a major public health problem not previously reported in Guatemala. Population representative studies in the highlands are needed to assess HIV prevalence in MSM, as well to improve current interventions.
all patients recovered without requiring immunoglobulin and/or blood transfusions.

Conclusion: In the HAART era, the presence of chronic anaemia in HIV-infected patients should alert the physician to the possibility of B19V infection especially during epidemics. There were no apparent relationships between the infecting genotype and the clinical course and this is the first report of genotype 3b in Rio de Janeiro.

P3.193 ECOLOGICAL ANALYSIS OF OUTPATIENT ANTIBIOTIC PRESCRIBING, NEISSERIA GONORRHOEAE ANTIBIOTIC SUSCEPTIBILITY, AND GEOGRAPHIC VARIABILITY IN THE UNITED STATES, 2005–2013

Robert D Kirkcaalco, 1Monina Bartoces, 2Olusegun O Soge, 3Grace Kubin, 4Carlos Del Rio, 5Edward W Hook, 6Stefan Riedel, 1John R Papp, 1Lauri A Hicks. 1Centres for Disease Control and Prevention, Atlanta, Georgia, USA; 2University of Washington, Seattle, Washington, USA; 3University of Houston, Houston, Texas, USA; 4Emory University, Atlanta, Georgia, USA; 5University of Alabama At Birmingham, Birmingham, AL, USA; 6Beth Israel Deaconess Medical Centre, Boston, USA

Introduction To what degree population-level antibiotic use contributes to Neisseria gonorrhoeae (NG) resistance in the US is unclear. We investigated whether outpatient prescribing is associated with NG antibiotic susceptibility.

Methods Using data from the Gonococcal Isolate Surveillance Project (GISP; a US surveillance system that samples male urethral isolates) during 2005–2013, we calculated annual geometric mean minimum inhibitory concentrations (MICs) of azithromycin, cefixime, and ceftriaxone by site. We used QuintilesIMS data (captures>70% of US outpatient prescriptions and projects to 100% coverage) to calculate annual cephalosporin and macrolide rates prescribing per 1000 men by each county corresponding to a GISP site. For descriptive analyses, we calculated site-specific medians of these measures. We constructed multivariable linear mixed models for each agent with annual prescribing rates as the exposure and one-year lagged geometric mean MIC as the outcome.

Results Annual geometric mean cefixime MICs increased from 0.009 µg/ml (2005) to 0.021 (2013), ceftriaxone from 0.005 (2006) to 0.01 (2007–2013), and azithromycin from 0.171 (2011) to 0.242 (2008). Western sites had the highest median cefixime MICs (0.018–0.03 by site); Southern sites had the lowest (0.016–0.019). Northeastern (0.298), Midwestern (0.258–0.314), and Western (0.136–0.295) sites had the highest median azithromycin MICs; Southern site had the lowest (0.1–0.234). Ceftriaxone MICs demonstrated little geographic variation. Southern sites had the most susceptible NG (lowest MICs), but highest median cephalexin (44–140 by site) and macrolides (98–244) prescribing rates. Western sites had the lowest cepheplorin (39–75) and macrolide (61–125) prescribing rates, Multivariable models did not demonstrate associations between prescribing and NG susceptibility.

Conclusion Using these data, we found no association between US antibiotic prescribing rates and NG susceptibility. Elucidation of factors contributing to resistance, including further investigation of antibiotic use, is warranted.

P3.194 INVESTIGATING HIV/AIDS MORTALITY IN THE STATE OF SAO PAULO (BRAZIL): A STRATEGY FOR INTERVENTION

SQ Rocha, SR Silva, DL Estevez, MV Tancredi, RA Souza, MCGG Ribeiro. STD/AIDS Reference and Training Centre, São Paulo – SP, Brazil

Introduction The response to the AIDS epidemic in the State of São Paulo contributes significantly for the positive results of the Brazilian National Program. There was a decrease of 71.6% in the State’s mortality rates between the years of 1995 and 2014, when the rate reached 6.5 per 1 000 inhabitants/year.

Methods Since 2014 Sao Paulo State’s STI/AIDS Programme has compiled investigative data on deaths of HIV-infected individuals, tracing profiles and evaluating causes of death and associated vulnerabilities.

Results From 1586 deaths investigated between 2013 and 2016, a significant ratio (66%) is under 50 years old and a considerable number (32%) of individuals survived until two years after the diagnosis. Late-diagnosis, late implementation of TARV and poor adhesion are notable among the deaths, as well as a significant ratio (29%) of substance-abusing individuals.

AIDS-defining illnesses (particularly tuberculosis) rank as the highest causes of death (55%) followed by non-AIDS-defining bacterial infections (18%), which are both predominant among the deaths of those patients with therapeutic disruption and/or advanced HIV infection. Causes unrelated to HIV and bacterial infections are predominant among patients with suppression of HIV-replication and recent CD4 count above 500 cells/mm³.

Conclusion Even in light of a positive context due to the decrease of MR, the oversight of deaths of HIV-infected individuals remains a fundamental practice for identifying vulnerabilities and works as a guiding principle for interventions that may contribute to a decrease in the number of avoidable deaths. The results indicate the relevance of actions towards early-diagnosis, monitoring of patient-enrollment and adhesion to services, timely start of antiretroviral therapy, continued oversight of patient-adhesion to medications and diagnosis as well as towards the treatment of potentially-avoidable conditions such as latent infection of tuberculosis and vaccination for pneumococci. Some groups - such as drug and alcohol abusing individuals - require a case-by-case approach.

P3.195 PREVALENCE OF SYphilIS AND HIV INFECTION DURING PREGNANCY IN INCARCERATED WOMEN AND THE INCIDENCE OF CONGENITAL SYphilIS IN BIRTHS IN PRISON IN BRAZIL

Rosa Maria Saares Madeira Domingues, 1Maria Do Carmo Leal, 2Ana Paula Estevens Pereira, 2Barbara Ayres, 3Alexandra Sanchez, 1Bernard Larouze, 1Instituto Nacional de Infectologia Evandro Chagas, Rio de Janeiro – RJ, Brazil; 2Departamento de Epidemologia e Metodos Quantitativos em Saude, Escola Nacional de Saude Publica SFR, Rio de Janeiro – RJ, Brazil; 3Centro de Referencia Professor Mello Fraga, Escola Nacional de Saude Publica (ENSP), Fundacao Oswal, Rio de Janeiro – RJ, Brazil; 4Sorbonne Universites, UPMC CNRS Paris 06/INSERM, PLEPS, Equipe D’Epidemologie Sociale, Paris, France

Introduction This study aimed to estimate the prevalence of syphilis and HIV infection during pregnancy, the mother to child transmission (MTCT) of syphilis and the incidence of congenital syphilis in incarcerated women in Brazil; to
