Conclusion The study suggests the association of hMR in sexual transmission of HIV. Presence of hMR in lower number of vaginal epithelial cells of Serodiscordant females prevented binding and HIV entry into these cells.

Introduction Cervical cancer is the 2nd most common cancer in the world whilst the incidence of cervical cancer continue to rise in Sri Lanka. It’s important to assess the knowledge and the awareness on the cancer and the HPV vaccine. The objective of this research was to assess the knowledge and awareness about the cervical cancers and HPV vaccine.

Methods A descriptive cross-sectional study was done on 326 Sri Lankan urban and sub-urban females using convenient sampling who were in the age between 14–39 years using a self-administered questionnaire.

Results (62.9%) of the participants, were from the age group 21–29. (50.8%) had an advance level education, 30.4% had an undergraduate level education. (55%) haven’t heard about a vaccine which could prevent cervical cancer, 51.2% knows that cervical cancers are common in Sri Lanka. 193 (59.2%) did not know that HPV is the most common cause for cervical cancers. When considering occupational level (p<0.001) and education level (p=0.001) played a key role in determining the awareness of HPV vaccine on women. Respondents from the government sector with a good education had more awareness on the HPV vaccine. 28% obtained information on HPV vaccine through health care professionals or the Internet. Only 4% have been vaccinated and reason for not getting a vaccine is due to lack of knowledge. Only 11.3% knew about the correct does for the vaccine.

Conclusion It’s evident that the knowledge and awareness is very low in terms of the vaccine.

Conclusion PrEP interest was high among FSWs along the Mexico-US border. Our findings suggest that the development of multi-purpose PrEP products and site-specific interventions that provide PrEP education and address substance use and clients’ perceptions as barriers to PrEP use may support FSWs’ future PrEP uptake.

Introduction Autoimmune and systemic diseases (ADs) were described in HIV infected patients and a classification by immune status was proposed.

Methods HIV-infected patients that presented an AD in the infectious diseases department of La Rabta University hospital in Tunis (Tunisia) were retrospectively included.

Results Four patients were included. The ADs were spondylarthropathy, Behçet disease and psoriasis. Two patients presented Behçet disease. In two patients, the AD preceded HIV infection and in the two others, HIV infection was diagnosed at the same time as the AD. In all cases, ADs occurred in patients with a CD4 T lymphocyte count of more than 200/mm³. No coinfection with hepatitis B or C viruses was diagnosed. Three patients received anti-inflammatory drugs and one patient received immunosuppressant treatment with good tolerance.

Conclusion AD and autoantibodies are present in HIV infection. AD may develop during acute viral infection (Stage I), with normal to low CD4 counts (Stage II). However, past a threshold where the CD4 count is profoundly low, AD cannot develop (Stage III). Following HAART, immune restoration (normal CD4 count) with possible altered immune regulation may lead to the emergence of AD (Stage IV). More studies are necessary to identify the subgroups of HIV-infected patients that may be prone to develop AD. Co-infection with hepatitis B or C viruses should be screened.
