P138 HIGH STI PREVALENCE AMONG HIV-EXPOSED WOMEN PLANNING FOR PREGNANCY IN RURAL, SOUTHWESTERN UGANDA

1Posha Chitneni*, 2Mwesesi Bosco Rwana, 3Moran Omwambazia, 4Kasey O’Neil, 5Deogratius Tokwaisiwe, 6Alice Najuma, 7Cathy Kyampwe, 8Sylva Natukunda, 9Adail Byamukama, 10Yona Mbalibulha, 11Paul Kato Kayebora, 12Angela Kaida, 13Lynn Matthews, 14Bigham and Women’s Hospital and Massachusetts General Hospital, Infectious Diseases, Boston, USA; 15Mbarara University of Science and Technology, Department of Internal Medicine, Mbarara, Uganda; 16Mbarara University of Science and Technology, Mbarara, Uganda; 17Massachusetts General Hospital, Center for Global Health, Boston, USA; 18Simon Fraser University, Vancouver, Canada; 19University of Alabama at Birmingham, Division of Infectious Diseases, Birmingham, USA

Background Many HIV-affected couples desire children. STIs increase risks of infertility, poor maternal and infant outcomes, and HIV acquisition. We introduced STI testing in southwestern Uganda to characterize STI epidemiology among HIV-exposed women planning for pregnancy.

Methods The Healthy Families PrEP study is enrolling 150 HIV-uninfected women planning for pregnancy with a partner known or suspected to be living with HIV. At enrollment, women are offered comprehensive safer conception counseling, including TDF/FTC as PrEP. We integrated STI testing for Chlamydia trachomatis (CT), Neisseria gonorrhoea (NG), Trichomonas vaginalis (TV) (via GeneXpert), and Syphilis (via immunochromatographic rapid testing confirmed by RPR). We calculated STI prevalence and compared differences among women with and without STI (Fisher’s exact test).

Results Between June 2018 and January 2019, 63 women completed baseline STI testing. Median age was 28 (IQR 24–31) years. Seventeen participants (27%) had STIs, including CT-14%, NG-3%, TV-8%, Syphilis-6%, and 5% with two STIs. Women with STI were less likely to report prior pregnancy (13/17 (76%) vs. 45/46 (98%), p=0.02) and trended towards being more likely to report prior stillbirth (4/17 (24%) vs. 3/46 (7%), p=0.08). Women with STI were less likely to report having relationship power to negotiate condom use (7/17 (41%) vs. 27/46 (59%), p=0.26) and were younger (median age 26 vs. 29). PrEP uptake was high in both groups (16/17 (94%) vs. 42/46 (91%), p=1).

Conclusion We describe a 27% curable STI prevalence among HIV-exposed women planning for pregnancy. Women with STI were less likely to have had a prior pregnancy and trended towards prior stillbirth, possibly due to undiagnosed STI. In an HIV-endemic setting with social pressures to conceive children, infertility may contribute to increased HIV and STI exposures and prevalence. These data highlight the importance of integrating STI testing into HIV prevention programs to maximize the health of women, children, and families.

P139 THE RACIAL IMPACT OF AIDS TRENDS AMONG WOMEN IN SAO PAULO, BRAZIL

Carmen Silvia Domingues*, Angélica Taya, Marcia Polon, Maria Tancredi. STI/AIDS Reference Center – Sao Paulo State Program of STI/AIDS, Sao Paulo Department of Health, Sao Paulo, Brazil

Background In the Sao Paulo State (SPS), the AIDS epidemic decreased among women, due to early diagnosis, antiretroviral use and prevention. This study aimed to analyze the trends of women living with AIDS (WLWA) and the HIV infection in pregnant women (PW-HIV) in the Sao Paulo City (SPC) and SPS, according to race/skin-color, from 2007–2016.

Methods Trend study using polynomial regression models performed with reported cases of WLWA and PW-HIV compared to SPC and SPS according to race/skin-color and diagnosis period. The annual number of WLWA and PW-HIV in each of the categories studied was considered as the dependent variable (Y), and the independent variable (X) was the time, represented by the calendar years, referring to the study period. The goodness of fit via $r^2$ and $p<0.05$ were used to determine which models and data were most appropriate.

Results In the period from 2007–2016, 18,571 AIDS cases in the SPS and 7,078 in the SPC were reported among women were analyzed. In the SPS, WLWA presented a decreasing linear trend with first order modeling, with a higher fall rate among white women [$Y=1,093–101X;r^2=0.97;p<0.001$] than in black [$Y=237–15X;r^2=0.88;p<0.001$], and mixed color/race [$Y=600–35X;r^2=0.89;p<0.001$]. In the SPC, the same trends were observed among white women [$Y=362–34X;r^2=0.97; p<0.001$], black [$Y=108–6X;r^2=0.81;p<0.001$], and mixed color/race [$Y=263–12X;r^2=0.86;p<0.001$]. For PW-HIV, 12,676 cases in the SPS and 4,160 in the SPC were analyzed. White PW-HIV showed a decreasing trend, being more expressive in the SPS [$Y=681–21X;r^2=0.89;p<0.001$] than in the SPC [$Y=191–5X;r^2=0.64;p=0.005$]. In the SPS and the SPC, among black and mixed color/race PW-HIV the trend presented stability.

Conclusion To reduce the social inequalities, the care network must discuss specific strategies to improve the access to health care services and antenatal care services for black and mixed color/race WLWA and PW-HIV, prevention measures, sexual and reproductive health care, including access to long-acting contraceptives.

P140 THE RISING HIV EPIDEMIC AMONG KEY POPULATIONS: AN URGENT NEED FOR A FOCUSED TARGETED PREVENTION RESPONSE IN PAKISTAN

1Faran Emmanuel, 2Baseer Achakzai, 3Tahira Reza. 1University of Manitoba, Centre for Global Public Health, Department of Community Health Sciences, WINNIPEG, Canada; 2National AIDS Control Program, Islamabad, Pakistan; 3Centre for Global Public Health, Islamabad, Pakistan

Background HIV Surveillance data has been used extensively to guide HIV prevention program in Pakistan since 2004. The 5th round of surveillance was conducted in 23 cities to determine the progression of the HIV epidemic, profile risk behaviors and program coverage among key populations to inform HIV prevention programs in Pakistan.

Methods A total number of 5,660 FSWs, 6,773 MSM, 5,191 Transgenders and 4,062 PWIDs participated in the study using diverse sampling techniques to draw representative samples. Behavioral data were collected using structured questionnaires while blood samples were tested using two rapid HIV tests following WHO protocol. Informed consent was obtained and all participants were linked with HIV programs. Moreover, all positive subjects were linked to HIV treatment care and support. International ethical guidelines were followed and ethical
