**Background** Brazil has a strong HIV prevention public health program since 1980s that includes continuous and free nationwide distribution of male and female condoms, rapid test triage, and education strategies. Even so, the detection rate of HIV has increased, achieving 14.3/1,000,000 individuals aged 15–24 years (2017). Regarding this alarming situation, we aimed to assess the HIV prevalence and associate characteristics in young Brazilian adults (aged 16 to 25 years).

**Methods** Data from POP-Brazil Study, a cross-sectional, nationwide, multicenter study with sexually active men and women who use the public health system in Brazil were obtained. Trained primary health care professionals asked participants about sociodemographic characteristics and presence of HIV. Additionally, they invited to undergo a rapid HIV test. Those individuals that did not answer the question or did not take the laboratory test were considered missing values. The measures were weighted by population size in each capital and by sex.

**Results** Of 8,581 participants, 3,009 do not provided information about HIV, and 49 (1.54%, CI95% 0.83%-2.25%) reported positivity or were reagent in the rapid HIV test, without significant differences between Brazilian regions. The positivity was significantly higher in men than women (2.7% vs. 0.6%, p<0.001), as well as in non-married participants (p<0.001), those with more than two partners in the last year (p<0.009), homosexual intercourse (p<0.001) or non-vaginal sexual behavior (p<0.001). The use of condom in the first sexual intercourse was not significant different between the groups of infection.

**Conclusion** The high prevalence of HIV is even more concerning taking into account the high proportion of missing individuals. Association of HIV with homosexual intercourse and non-vaginal sexual behavior were more frequently in male. Despite the sustained Brazilian public health program, this particular age range need to be on the focus of prevention strategies.

**Disclosure** No significant relationships.

**P153** ARE PARTURIENT WOMEN ON ANTI-RETROVIRAL THERAPY COMPLYING WITH THE RECOMMENDED SIX-MONTHS EXCLUSIVE BREASTFEEDING?

1Anthony Ajayi*, 2Oladele Adeniyi. 1University of Fort Hare, Sociology, East London, South Africa; 2Walter Sisulu University, Family Medicine, East London, South Africa

10.1136/sextrans-2019-sti.317

**Background** Exclusive breastfeeding is recommended for the first six months in HIV-exposed infants in sub-Saharan Africa. This cost-effective and high impact strategy has proven to promote healthy infant growth, development and survival of children in resource poor settings. Despite antenatal and postnatal counselling and support on the choice of feeding for HIV-exposed infants, the practice of EBF remains low in sub-Saharan Africa. Given the paucity of data on the topic in the study setting, we examined the prevalence of six-month exclusive breastfeeding.

**Methods** We followed up parturient women enrolled in the East London Prospective Cohort Study with the aim of determining the rate and determinants of exclusive breast feeding in the region. Relevant items on demographic, lifestyles and duration of EBF were obtained using structured interviews. Binary logistic analysis was fitted to examine the significant determinants of EBF.

**Results** Six infants died within the first six months in the cohort. Of the parturient women with complete responses (469), the prevalence of exclusive breastfeeding for the recommended six months was 32% (n=150). Women who were unemployed in the past 12 months had a higher likelihood of exclusively breastfeeding their infants for 6 months compared to women who were employed [AOR:1.68, CI:1.08–2.63]. Also, women who did not consume alcohol beverages in the past 12 months had a higher odds of exclusively breastfeeding their infants [AOR:1.77, CI:1.12–2.78]. Adherence to antiretroviral therapy [AOR:0.83; CI:0.53–1.29], disclosure of HIV serostatus to sexual partners [AOR:0.98; CI:0.51–1.94] and marital status [AOR:1.32; CI:0.86–2.02] were not significantly associated with exclusively breastfeeding of infants for six months.

**Conclusion** Very low rate of exclusive breastfeeding for six months among HIV-infected parturient raises serious concern for mother-to-child transmission, morbidity and mortality of exposed-infants in the study setting. Intervention strategies to promote and monitor compliance with exclusive breastfeeding recommendations require targeted research.

**Disclosure** No significant relationships.

**P154** DIFFUSE SKewing OF TH17/TREg RATIO IN THE ANORECTAL MUCOSA OF HIV+MSM WITH HPV-ASSOCIATED DYSPLASIA

1Yoojin Choi, 2Irving Salit, 1Sarah Sgro, 2Edward Weiss, 2Colin Kovacs, 3Rachelle Paquette, 5Matian Claudio, 4Alberto Severini, 5Rupert Kaul. 1University of Toronto, Toronto, Canada; 2University Health Network, Toronto, Canada; 3Maple Leaf Medical Clinic, Toronto, Canada; 2Public Health Agency of Canada, Winnipeg, Canada

10.1136/sextrans-2019-sti.318

**Background** Anal Human Papillomavirus (HPV) infection is common in MSM. While most HPV infections resolve spontaneously, some persist and cause anal intraepithelial neoplasia (AIN) that can progress to anal cancer. To better understand the mucosal immunopathogenesis of HPV/AIN, we compared mucosal T cell subsets between AIN-free mucosa and AIN lesions within HIV+ART+ MSM.

**Methods** Anal swabs from 46 participants were used to 1) screen for 46 mucosal HPV types by microsphere-based genotyping and 2) test for HIV RNA levels by RT-PCR.AIN-free mucosa was biopsied, and (where applicable) additional biopsies were taken from histology-confirmed areas of AIN. Treg markers (CD25, FoxP3) and a Th17 marker (CCR6) were assessed by flow cytometry. Statistical comparisons were assessed between groups (Mann-Whitney) and within the same individual (Wilcoxon).

**Results** Th subsets were first compared between clinically normal mucosa and AIN lesions within AIN+ individuals, and no lesion-specific alterations were apparent. When we compared clinically normal mucosa between study groups, participants with high-grade AIN had a reduced Th17/Treg ratio compared to participants with no AIN (HGAIN= 7.83, No AIN= 19.75; p= 0.007) or participants with low-grade AIN.
