**P509 USE OF INTERNET/MOBILE DATING APPS TO FIND SEX PARTNERS AMONG A NATIONALLY REPRESENTATIVE SAMPLE OF MEN WHO HAVE SEX WITH MEN**

1Rachel Kachur*, 2Casey Copen, 3Frank Strona, 4Bruce Furness, 5Kyle Bernstein, 6Matthew Hogben, 1Centers for Disease Control and Prevention, Division of STD Prevention, Brookhaven, USA; 2Centers for Disease Control and Prevention, Division of STD Prevention, Atlanta, USA; 3Centers for Disease Control and Prevention, Division of STD Prevention, San Francisco, USA; 4Centers for Disease Control and Prevention, Division of STD Prevention, Washington DC, USA; 5Centers for Disease Control and Prevention, Atlanta, USA

Background Associations between online sex seeking and increased risk for STDs and HIV among men who have sex with men (MSM) typically rely on convenience samples. We examined the prevalence of internet and mobile app use for finding sex partners among a nationally representative sample of MSM.

Methods We analyzed 2011–2017 data from the National Survey of Family Growth, a nationally representative sample of the civilian, non-institutionalized US population (15–44 years). The analytic sample was comprised of males who reported one or more same-sex partners in the past year. We also assessed associations between online sex-seeking and STD risk, sexual health service use, and condom use.

Results Of 13,320 male respondents, 442 (3.0%) reported sex with a man in the past year, of whom 227 (53.7%) had met one or more same-sex partners in the past year. We also found no differences by age, education, race/ethnicity or socioeconomic status. MSM with online partners were more likely to identify as gay (69.5% vs 49.4%, p <0.02). They also reported more sex partners over-the-counter chemsex drugs; STI positivity in this group was 44% (20/45). The only factor independently associated with STI was the use of three or more chemsex drugs (aOR: 4.13, 95% CI:1.77–9.62).

Conclusion This study shows that chemsex is prevalent among MSM visiting the STI clinic outside major cities in the Netherlands, suggesting that health services in both urban and non-urban areas should be aware of and informed on chemsex. MSM who used multiple drugs are at particular risk for STI, indicating a special need for STI prevention and care in this group.

Disclosure No significant relationships.

**P510 CHEMSEX AMONG MEN WHO HAVE SEX WITH MEN IN A MIXED URBAN-NON-URBAN AREA AND ASSOCIATIONS WITH SEXUALLY TRANSMITTED INFECTIONS**

Ymke Evers, Genevieve Van Liere, Christian Hœbe*, Nicole Dukers-Muijters. Public Health Service South Limburg, Maastricht University Medical Center (MUMC) Sexual Health, Infectious Diseases and Environmental Health, Medical Microbiology, Care and Public Health Research Institute (CAPHRI), Heenelen, Netherlands

Background The intentional use of drugs to have sex – chemsex – among men who have sex with men might contribute to the high STI prevalence in this group. Limited data is available on chemsex outside major cities in Europe. The current study investigated the use of a wide variety of drugs during sex in a mixed urban-non-urban area in the Netherlands and their associations with STI.

Methods At two Dutch STI clinics, 350 MSM were recruited and 250 MSM completed an online questionnaire in 2018. Questionnaire data were linked to patients’ most recent STI laboratory test results. Chemsex was defined as using cocaine, crystal meth, designer drugs, GHB/GBL, ketamine, speed, or XTC/MDMA during sex in the preceding six months. The use of other drugs was also assessed. Determinants (any drug use, chemsex, specific drugs, number of drugs, combining, and frequency) potentially associated with STI were assessed using multivariable logistic regression analyses adjusting for sociodemographic characteristics and sexual history.

Results Chemsex was reported by 35% (95%CI: 29–41) of the 250 participants. XTC/MDMA (27%; 68/250) and GHB/GBL (26%; 64/250) were the most used drugs. STI positivity was 33% (29/87) in MSM engaging in chemsex and 12% (12/163) in MSM not engaging in chemsex (p<0.001). Half of MSM engaging in chemsex (45/87) used three or different chemsex drugs; STI positivity in this group was 44% (20/45). The only factor independently associated with STI was the use of three or more chemsex drugs (aOR: 4.13, 95% CI:1.77–9.62).

Conclusion No significant relationships.

**P511 SURVEILLANCE OF LYMPHOGRANULOMA VENEREUM AMONG MEN WHO HAVE SEX WITH MEN ATTENDING STI CLINICS IN ALBERTA, CANADA, 2018**

1Jennifer Gratix, 1John Ninban, 2Alberto Severini, 2Jennifer Beirnes, 3Prenilla Naidu, 4Angel Chu, 5Ameeta Singh, 1Petra Smyczek*. 1Alberta Health Services, Centralized STI Services, Edmonton, Canada; 2Public Health Agency of Canada, National Microbiology Laboratory, Winnipeg, Canada; 3Provincial Laboratory for Public Health, Edmonton, Canada; 4Alberta Health Services, Calgary STI Clinic, Calgary, Canada; 5University of Alberta, Internal Medicine, Edmonton, Canada

Background Lymphogranuloma venereum (LGV) is a sexually transmitted infection (STI) caused by Chlamydia trachomatis (CT) biotypes L1-3, which has been increasingly reported among men who have sex with men (MSM). Our study aimed to establish a surveillance system among MSM attending STI clinics in Alberta, Canada to determine prevalence and characteristics of cases.

Methods CT NAAT (Genprobe Apta NA COMBO 20 Assay) positive specimens from all anatomical sites among MSM attending three STI clinics in Alberta, Canada were tested for LGV. Demographic, clinical, and sexual behaviours of cases were extracted from the provincial reporting database. Clinic-stratified analysis was performed to identify differences in sample characteristics using Chi-square or Fisher’s exact test.

Results A total of 340 specimens from 299 CT cases were tested for LGV. CT cases were reported from Calgary (52.8%; n=158), Edmonton (46.2%; n=138), and Fort McMurray (1.0%; n=3). There were no significant differences in
