(p<0.001) whereas G1407 genogroup was associated with MIC=0.125 mg/L for CFX (p=0.001), resistance to CIP PEN (p=0.016) and TET (p<0.001). Isolates that shared the same \( tbpB \) 29 allele were associated with resistance to AZT (p=0.008) and PEN (p=0.035). ST338 was associated with \( bla_{TEM-1} \) gene (p<0.001) and tetM (p=0.006), whereas the cluster sharing the same \( tbpB \) 137 allele was associated with tetM gene.

**Conclusion** This study showed high rates of resistance to PEN, TET and CIP associated with persistence and dissemination of gonococcal strains resistant to CIP and plasmid resistance to PEN and TET. Despite the high resistance profile to CIP and plasmid resistance in the analyzed Kenyan GC.

**Disclosure** No significant relationships.

**GYRA AND PARC MUTATIONS IN FLUOROQUINOLONE-RESISTANT NEISSERIA GONORRHOEAE ISOLATES FROM KENYA**

1Mary Kivita*, 2Margaret Mbuchi, 3Fredrick Eyase, 4Wallace Bulimo, 5Cecilia Kyanya, 6Valerie Ondo, 2Simon Muniruthi, 7Ben Andagali, 8Wilton Mbinda, 9Olusegun Soge, 10MKC Mediland, 11Willy Sang Sang, 12James Mancuso, 13Jomo Kenyatta University of Agriculture and Technology, Institute for Biotechnology Research, Thika, Kenya; 14US Army Medical Research Directorate-Kenya, Village Market, Nairobi, Kenya; 15Karanta University, Karanta, Kenya; 16University of Washington, Global Health, Seattle, USA; 17University of Washington, Epidemiology, Seattle, USA

**Background** Phenotypic fluoroquinolone resistance was first reported in Western Kenya in 2009 and later in Coastal Kenya and Nairobi. Until recently gonococcal fluoroquinolone resistance mechanisms in Kenya had not been elucidated. The aim of this paper is to analyze mutations in both GyrA and ParC responsible for elevated fluoroquinolone MICs in Neisseria gonorrhoeae (GC) isolated from heterosexual individuals from different locations in Kenya.

**Methods** Antimicrobial Susceptibility Tests were done on 84 GC in an ongoing STI surveillance program. Of the 84 isolates, 22 resistant to two or more classes of antimicrobials were chosen for analysis. Antimicrobial susceptibility tests were done using E-test and the results were interpreted with reference to European Committee on Antimicrobial Susceptibility Testing (EUCAST) standards. The isolates were sub-cultured and whole genomes sequenced using Illumina platform. Reads were assembled de novo using Velvet, and mutations in the GC Quinolone Resistant Determining Regions identified using Biodit sequence alignment editor. Single Nucleotide Polymorphism based phylogeny was inferred using RaxML.

**Results** Double GyrA mutations; S91F and D95G/D95A were identified in 20 isolates. Of these 20 isolates, 14 had an additional E91G ParC mutation and significantly higher ciprofloxacin MICs (p=0.0044*). On the contrary, norfloxacin MICs of isolates expressing both GyrA and ParC QRDR mutations were not significantly high (p=0.82) compared to MICs of isolates expressing GyrA mutations alone. No single GyrA mutation was found in the analyzed isolates, and no isolate contained a ParC mutation without the simultaneous presence of double GyrA mutations. Maximum likelihood tree clustered the 22 isolates into 6 distinct clades.

**Conclusion** Simultaneous presence of mutations in ParC and GyrA has been reported to increase gonococcal fluoroquinolone resistance from different regions in the world. Our findings indicate that GyrAS91F, D95G/D95A and ParC E91G amino acid substitutions mediate high fluoroquinolone resistance in the analyzed Kenyan GC.

**HIGH AZITHROMYCIN RESISTANCE AND DECREASING CEFTRIAXONE SUSCEPTIBILITY IN NEISSERIA GONORRHOEAE IN SHENZHEN (2010–2017), CHINA**

1Feng Wang*, 1Yizhu Li, 2Lijun Zhang, 3Jing Huang, 4Yueping Yin. 1Shenzhen Center for Chronic Disease Control, STD Control Laboratory, Shenzhen, China; 2Shenzhen Maternal and Children Health Care Hospital, Shenzhen, China; 3Shenyang Pharmaceutical University, Shenyang, China; 4National Center for STD Control, Chinese Center for Disease Control and Prevention; Institute of Dermatology, Chinese Academy of Medical Sciences and Peking Union Medical College, Nanjing, China

**Background** Emergence and development of resistance in Neisseria gonorrhoeae (NG) to antibiotics has become a major public health problem worldwide. The aim of our study was to determine the antimicrobial susceptibility, especially ceftriaxone and azithromycin, and molecular epidemiological typing of NG isolates in Shenzhen, China.

**Methods** A total of 1,282 NG isolates were collected from Shenzhen, between 2010 and 2017. The minimum inhibitory concentrations (MICs) of NG isolates were determined from the agar dilution method. Resistance to azithromycin (AZM-R) was defined as MIC $\geq$ 1.0 mg/L, and decreased susceptibility to ceftriaxone (CRO$^B$) was defined as MIC $\geq$ 0.125 mg/L. Isolates were genotyped using Neisseria gonorrhoeae multi-antigen sequence typing (NG-MAST).

**Results** Among the isolates, 5.0% showed CRO$^B$, 17.3% was AZM-R and 1.3% was both CRO$^B$ and AZM-R. Increasing ceftriaxone MICs was found from 2010–2014 to 2015–2017 [ridit value: 0.385; 95% confidence interval (95%CI): 0.539–0.611], but not for CRO$^B$ and AZM-R. The proportions of isolates resistant to ciprofloxacin (97.4%, increasing from 96.6% in 2010–2014 to 98.8% in 2015–2017) and penicillin (68.2%, increasing from 60.6% in 2013–2014 to 73.5% in 2015–2017) were increasing, but PPNG was decreased. All isolates were susceptible to spectinomycin. Genogroup 5308 was inversely association associated with AZM-R; the corresponding odds ratio (95%CI) was: 0.098 (0.013–0.747).

**Conclusion** The founding of increasing ceftriaxone MICs over the time and high proportions of AZM-R in Shenzhen region calls for reevaluation dual therapy. Timely and efficient surveillance with isolates characterization and changes of susceptibility over time is essential.
