($p < 0.001$). In the interim, PrEP was widely implemented across Australia. Using interview data, we generated two themes describing condom use. Some sex workers and all of the clients we interviewed strictly refused to engage in condomless commercial sex. This strictness, however, extended only to anal sex (several participants laughed at using condoms for oral sex) and commercial encounters (many men were willing to forgo condoms for personal sex). Most male sex workers, however, were highly pragmatic about condoms. They described assessing the commercial risks-benefits of condoms, and while men were aware that condomless sex put them at risk for STIs other than HIV, they balanced that risk against increased earning potential: sex workers consistently reported charging more for condomless sex. This approach was characterized as a 'cash buffer' to compensate for the risk of being unable to work following a STI diagnosis.

Conclusion Although condom use has shifted dramatically among male sex work communities in Australia, to some they remain an important safer sex strategy. HIV PrEP and market forces have increased STI risk among male sex workers, making them ideal candidates for STI antibiotic prophylaxis.

HIGH PREVALENCE OF CONDOMLESS ANAL INTERCOURSE AMONG FEMALE SEX WORKERS IN IRAN

¹Mohammad Karamouzian*, ²Azam Rahmani, ³Mostafa Shokoochi, ³Hamid Sharifi, ⁴Ali Mirzazadeh. ¹BC Center on Substance Use, Vancouver, Canada; ²Tehran University of Medical Sciences, Tehran, Iran; ³WHO Collaborating Center for HIV/STI Surveillance, Kerman, Iran; ⁴UCSF, San Francisco, USA

10.1136/sextrans-2019-sti.777

Background Condomless sex and particularly anal intercourse (AI) with partners and clients are among the primary drivers of the HIV epidemic among female sex workers (FSW) in Iran. However, little is known about AI prevalence and its correlates among FSW in Iran.

Methods Data were obtained from a bio-behavioral surveillance survey of 1347 FSW conducted across 13 major cities in Iran in 2015. FSW were eligible if they (i) were ≥ 18 years of age, (ii) reported penetrative sex with more than one client in the previous year. Data were collected through one-on-one interviews using a standardized risk assessment questionnaire. A modified Poisson regression model was used to examine the correlates of recent (i.e., past-month) HAS and adjusted prevalence ratio (APR) and 95% confidence intervals (CI) were reported (analytic sample: 1337).

Results Recent AI was reported by 18.5% (95% CI: 13.0, 25.6) of the participants; of whom, 196 (80%) reported inconsistent condom use during their AIs in the previous month. Recent AI was positively associated with younger (≤ 18) age (APR: 1.24; 95% CI: 1.06–1.59), history of group sex in the previous month (APR: 1.62; 95% CI: 1.08–2.44), higher number of clients in the previous month (APR: 2.35; 95% CI: 1.38–4.00), and weekly use of alcohol (APR: 1.62; 95% CI: 1.12–2.34). Conversely, recent AI was negatively associated with being married (APR: 0.52; 95% CI: 0.34–0.80) and having had protected sex with their last client (APR: 0.73; 95% CI: 0.54–0.97).

Conclusion About one in five FSW reported engaging in recent AI; most of which were condomless. AI was more frequent among younger FSW and those with higher number of clients and problematic Alcohol use. Harm reduction and condom promotion efforts in Iran should include effective packages to address high prevalence of unsafe AI and re-emphasize the importance of condom use for both FSW and their partners/clients.

HIV TESTING AND UNDIAGNOSED FRACTION AMONG ADOLESCENT GIRLS AND YOUNG WOMEN BY ENGAGEMENT IN SEX WORK IN MOMBASA, KENYA

¹Huiting Ma, ²Parinita Bhattacharjee, ³Linwei Wang, ⁴Vernon Mochache, ⁵Helgar Musyoki, ⁶Peter Gichangi, ⁷James Blanchard, ⁸Paul Sandstrom, ⁸Christina Daniuk, ⁷Stephen Moses, ⁷Marissa Becker*, ⁹Sharmistha Mishra. ¹St. Michael's Hospital, Centre for Urban Health Solutions, Toronto, Canada; ²University of Manitoba, Centre for Global Public Health, Nairobi, Kenya; ³St. Michael's Hospital, Toronto, Canada; ⁴University of Maryland, Centre for International Health, Education and Biosecurity, Berwyn, USA; ⁵National AIDS and STI Control Programme, Nairobi, Kenya; ⁶University of Nairobi, Nairobi, Kenya; ⁷University of Manitoba, Centre for Global Public Health, Department of Community Health Sciences, Winnipeg, Canada; ⁸Public Health Agency of Canada, Winnipeg, Canada; ⁹St. Michael's Hospital, Li Ka Shing Knowledge Institute, Toronto, Canada

10.1136/sextrans-2019-sti.778

Background Traditional HIV prevention and testing services are generally designed to either reach female sex workers or to reach adolescent girls and young women (AGYW), but not both. We sought to compare the levels and determinants of HIV testing, and the prevalence of undiagnosed HIV across subsets of AGYW in Kenya.

Methods We used data from *Transitions*, a 2015 cross-sectional survey of 1,299 women age 14–24 years who frequented hot-spots associated with formal sex work in Mombasa, Kenya. We compared the prevalence and frequency of recent HIV testing in the previous year between AGYW involved in sex work (YSW, N=408) versus those who did not sell sex (NSW, N=891), and excluding those diagnosed with HIV ≥ 1 year before the survey. We used logistic regression model to identify univariate determinants of recent testing in each group. We then compared the prevalence of undiagnosed HIV among YSW and NSW living with HIV.

Results Overall, 72% reported a recent HIV test: 85% YSW and 65% NSW ($p < 0.01$), of whom, 42% of YSW and 27% of NSW tested at least twice in the previous year ($p < 0.01$). Shared determinants of recent HIV testing by subgroup included: older age (Odds Ratios [95% Confidence Intervals] for SW: 2.8 [1.6–5.0]; NSW: 2.3 [1.7–3.0]), ever contacted by peers/staff from a non-governmental/community-based organization (5.3 [1.6–32.8]; 1.9 [1.1–3.8]), prior pregnancy (1.8 [1.1–3.2]; 2.6 [1.8–3.6]), and recent STI treatment (6.2 [2.2–25.9]; 1.9 [1.3–3.0]). N=37/365 (10%) of YSW and N=30/828 (4%) NSW were living with HIV, of whom only 27% (N=10/37), and 30% (N=9/30) were diagnosed and aware ($p = 0.79$ subgroup comparison).

Conclusion Shared determinants of testing suggest that reaching across high-risk AGYW via hotspot based strategies could fill gaps left by traditional HIV prevention and testing services.
