Background The aim of this study was to develop and externally validate a prognostic model for survival in people living with HIV/AIDS (PLWHA) initiating ART based on two large population-based cohorts in China.

Approach The derivation cohort consisted of PLWHA treated between February 2004 and December 2019 in a tertiary center in Guangzhou, South China, and validation cohort of patients treated between February 2004 to December 2018 in another tertiary hospital in Shenyang, Northeast China. We assessed 20 candidate predictors for an endpoint of death from all causes. The prognostic model was developed from a multivariable cox regression model with predictors selected using the least absolute shrinkage and selection operator (Lasso). To assess the model’s predictive ability, we quantified the discriminative power using the concordance (C) statistic and calibration accuracy by comparing predicted survival probabilities with observed survival probabilities estimated with the Kaplan-Meier method.

Outcomes The derivation cohort included 16481 patients and the external validation cohort comprised 5751 participants. The final model included 10 predictors: age, body mass index, route of HIV acquisition, coinfection with tuberculosis, coinfection with hepatitis C virus, haemoglobin, CD4 cell count, platelet count, aspartate transaminase, and plasma glucose. The C-statistic was 0.84 (95% confidence interval 0.82–0.85) in internal validation after adjustment of optimism and 0.84 (0.82–0.87) in external validation, which remained consistently above 0.75 in all landmark time points within five years of follow up when using time-updated laboratory measurements. The calibration accuracy was satisfactory in both derivation and validation cohorts.

Innovation and Significance We developed and externally validated a model to predict long-term survival in PLWHA on ART, which could be applied to individualized patient counseling and management during treatment, and future innovative trial design.

Results 557 cases of syphilis, including 380 (68%) ES and 177 (32%) LS cases, were diagnosed in 553 individuals (454 men, 99 women). Syphilis diagnoses increased over time; early syphilis cases increased 26% annually (p<0.001). Median age (years) was 32 (IQR=19–47) for ES patients and 39 (IQR=20–46) for LS patients. ES patients, when compared with LS patients, were more likely to be male (338/380 [89%] vs. 120/177 [68%]; OR 2.44, 95%CI=2.44–6.00), <35 years old (226/286 [79%] vs. 154/271 [57%]; OR 2.86, 95%CI=1.97–4.15), Australia-born (213/380 [56%] vs. 43/177 [24%]; OR 3.97, 95%CI=2.67–5.92), previously infected with syphilis (66/380 [17%] vs. 10/177 [6%]; OR 3.51, 95%CI=1.76–7.01), chemsex-users (72/380 [19%] vs. 4/177 [2%]; OR 10.11, 95%CI=3.63–28.17), PrEP-users (70/327 [21%] vs. 6/170 [4%]; OR 7.44, 95%CI=3.16–17.54) and HIV co-infected (53/380 [14%] vs. 7/177 [4%]; OR 4.83, 95%CI=2.14–10.89). Multivariable regression modelling indicated that these same ES-associated variables remained significant in men (p<0.05).

Conclusions Male gender, age <35 years, Australia-born, use of chemsex or PrEP, HIV co-infection and previous syphilis infection are risk factors associated with ES at WSSHHC.

**INFLUENCE OF THE COVID-19 PANDEMIC ON THE EPIDEMIOLOGY AND RESISTANCE OF NEISSERIA GONORRHOEAE IN AUSTRIA**

U Fuernkranz*, M Haller, A Stary. Pilzambulatorium Schoeselgasse, Vienna, Austria

Background Gonorrhoea is a health threat, infection levels and drug resistances increased over the last decades. The COVID-19 pandemic that hit Austria in 2020 led to several lockdown events such as closing of bars, clubs, hotels and the order to stay at home. The current study was designed to elucidate the influence of these measures in order to curtail the pandemic on the number of N. gonorrhoeae diagnosed and their respective resistance patterns.

Methods Retrospective data of patients positive for N. gonorrhoea and resistances to ceftriaxone, cefixime, azithromycin and penicillin were compared using data from 2019 and 2020 collected in and sent to the Outpatients Centre for Infectious Venero-dermatological Diseases in Vienna. Resistance testing was carried out by means of the Etest®; MIC values were interpreted according to EUCAST guidelines.

Results Numbers of patients tested positive for N. gonorrhoea declined dramatically from 639 in 2019 to 381 in 2020. The most prominent reduction was during the first lockdown (March to May 2020), with half as many gonococcal infections compared to this period in 2019. The second lockdown (November/December 2020) did not result in significantly lower numbers of gonococcal infected patients. In both years, no ceftriaxone-resistant isolate was detected. However, 2.3% of isolates from women showed borderline susceptibility (MIC = 0.094 and 0.125μg/ml), compared to 0.4% of isolates from men. During the two years of evaluation, cefixime and azithromycin resistant strains decreased (4% to 0% and 19% to 7%, respectively), while penicillin-resistant strains increased from 9% to 20%.
Abstracts

Conclusion The first lockdown resulted in a decrease of 62.7% of infected individuals. A remarkable decrease of resistant gonococcal strains to azithromycin and no resistance to ceftriaxone occurred in 2020. This is in contrast to an increase of resistances until 2019. Increasing numbers of isolates of women approached the MIC breakpoint for ceftriaxone.

**P351** CLINICAL PRESENTATIONS OF SYPHILIS DIAGNOSED AT WESTERN SYDNEY SEXUAL HEALTH CENTRE, 2015–2019

Y Hughes*, 1C Chung, 2,3 Zablotska-Manos, 1,2,3 D Lewis. 1Western Sydney Sexual Health Centre, Parramatta, Australia; 2Westmead Clinical School, Westmead, Australia; 3Marie Bashir Institute for Infectious Diseases and Biosecurity, Westmead, Australia

Objective: To investigate and identify the detection capability of syphilis in the STD (sexually transmitted disease) laboratories in Guangdong, China.

Method: An External quality assessment (EQA) of syphilis tests was performed and an online questionnaire surveys on tests and screening algorithms were conducted. Three positive and two negative EQA panels were prepared for qualitative or quantitative test of Nontreponemal tests (NTT) and Treponemal test (TT). The samples were distributed to all participants in October 2019 and the results were reported within one month and analyzed by Guangdong Central STD Laboratory through an online quality assessment software.

Results: A total of 838 laboratories participated in the program, which come from different STD clinics, including primary, secondary and tertiary general hospitals, Maternal and Child Health Care Hospitals and CDC from the provincial, prefecture and county levels in Guangdong. The results showed that overall coincidence rate of the 838 participated laboratories was 98.0%. The coincidence rate of NTT were that 99.3% of qualitative test and 96.7% of quantitative test. Coincidence rate of qualitative TT were 99.3%. There were 286 laboratories reported the quantitative TT results, with an overall coincidence rate of 94.7%. Toluidine red unheated serum test (TRUST) was the most used NTT, and Treponema pallidum particle assay (TPPA) popularly chosen as Treponemal test. There were 273 laboratories returned a second survey on syphilis screening algorithms. Among them, 118 (43.2%) laboratories adopted the traditional screening, 81 (29.7%) laboratories adopted the reverse screening, and 64 (23.4%) laboratories employed two algorithms simultaneously. Moreover, 10 (3.7%) laboratories adopted the ECDC (European Centre for Disease Control and Prevention) algorithm.

Conclusion: Laboratories in Guangdong Province have great capabilities of syphilis diagnosis, especially in the CDC and the Maternal and Child Hospitals. Traditional screening is the most used algorithm, while the use of reverse screening is increasing.

**P355** THE PERFORMANCE OF LABORATORY-BASED DIAGNOSTIC ASSAYS TO DIAGNOSE PRIMARY SYPHILIS CASES AT WESTERN SYDNEY SEXUAL HEALTH CENTRE, 2015–2019

Y Hughes*, 1C Chung, 2,3 Zablotska-Manos, 1,2,3 D Lewis. 1Western Sydney Sexual Health Centre, Parramatta, Australia; 2Westmead Clinical School, Westmead, Australia; 3Marie Bashir Institute for Infectious Diseases and Biosecurity, Westmead, Australia

Background: Treponema pallidum subsp. pallidum infection (TP) may be diagnosed either directly by dark-field microscopy (DFM) or polymerase chain reaction (PCR) assay, or indirectly by serology. TP PCR and serology are currently the mainstay of laboratory-based diagnosis due to technical challenges associated with DFM. We describe the performance of TP PCR and serology in the diagnosis of primary syphilis at Western Sydney Sexual Health Centre (WSSHC).

Methods: This is a retrospective study of primary syphilis cases diagnosed at WSSHC over a five-year period (2015–2019). Medical case records were reviewed to extract laboratory results. Patients without a prior history of syphilis were screened with either an enzyme-linked immunosorbent total antibody assay (EIA, WSSHC-associated laboratory) or a
